1 Introduction

Consider the equations

$$2108436491907081488939581538^2 = 4445504440405440505004450045555054500055550554550445444$$

and

$$101000000001040100000000101^2 = 10201000000021010020000011022100100000210100200000010201.$$

The common property of the numbers on the left hand sides is that their squares consist of three different digits only. The origin of the question of squares with few different digits dates back at least to 1991, see [4, Exercise 2.2] where squares consisting entirely of the three digits 2, 4, and 8 are considered. In [3, Problem F24] the question of Shin Hitotumatu whether there are only finitely many squares, not ending with zero, with just two different decimal digits, is reported. Today only 24 such numbers are known, the largest being $81619^2 = 6661661161$. Since there is not so much to discover for two digits, people moved over to the study of squares with three different digits. A corresponding webpage, started in 1996 and still updated, is www.worldofnumbers.com/threedigits.htm. And indeed, there are still things to discover. The two examples, mentioned in the first few lines, were unknown so far and the second can even be generalized to a 2-parameter family yielding an infinite number of examples.

Of course, we should not let ourselves get distracted by our fingers and toes. So, given an integer $B \geq 2$, called *base* or *radix*, each positive integer N can be uniquely written as

$$N = \sum_{i=0}^{n-1} a_i B^i,$$

where $a_i \in \{0, 1, \dots, B-1\}$ are called *digits* for all $0 \leq i \leq n-1$, $n \in \mathbb{N}_{>0}$ is the *length*, which is

determined via the condition $a_{n-1} \neq 0$. The *base- B -representation* on N is denoted by

$$\varphi_B(N) := [a_{n-1}, a_{n-2}, \dots, a_1, a_0]_B,$$

where we sometimes drop the commas and the square brackets with index B whenever the base is clear from the context. The digit a_0 is also called the *last digit* and $l_B(N) := n$ the *length* of N (in base B).

Here we are interested in positive integers N such that the base- B -representation of N^2 contains exactly three different digits, i.e., if $N^2 = [b_{n-1}, \dots, b_0]_B$, then we require $|\{b_i : 0 \leq i \leq n-1\}| = 3$. As an abbreviation we set $D_B(N) := \{a_i : 0 \leq i \leq n-1\}$, where $N = [a_{n-1}, \dots, a_0]_B$. An example in base $B = 10$ is given by $N = 130834904430015239$, $N^2 = 171177722172112212111721777222712$, and $D_{10}(N^2) = \{1, 2, 7\}$. If $0 \in D_B(N^2)$, then $D_B((B^m \cdot N)^2) = D_B(N^2)$ for each positive integer N and each non-negative integer m . So, we restrict ourselves to the cases where N is not divisible by B .

In principle, for $B \geq 4$ positive integers N with $|D_B(N^2)| = 3$ are rather rare. However, several “infinite patterns” exist. An example for base $B = 10$ is given by

$$[1 \underbrace{6 \dots 6}_k 5]^2 = [2 \underbrace{7 \dots 7}_k \underbrace{2 \dots 2}_{k+1} 5], \quad (1)$$

where $k \geq 0$.

The aim of this paper is to summarize the current knowledge on squares with three digits, scattered around webpages and newsgroup posting, and to add a few new insights. While we will mostly focus on the base $B = 10$, several results are presented for general values of B . The used mathematical tools are completely elementary. However, we give complete proofs of all statements or explicitly state them as conjectures. The closest “research paper”, that we are aware of is [1]. Here the authors determine all integers N such that N^2 has at most three non-zero digits in base $q \in \{2, 3, 4, 5, 8, 16\}$. For odd primes q , $u > v > 3$, and $r^2, s, t < q$ they also determine all solutions of the Diophantine equation

$$N^2 = r^2 + s \cdot q^u + t \cdot q^v.$$

We are not aware of any number theoretic tools that might be applied if the non-zero digits are not sparse but they attain few distinct values only.

The remaining part of this paper is structured as follows. In Section 2 we briefly consider the computation of the digits of a square. Infinite patterns of integers whose squares consist of just three decimal digits are the topic of Section 3. Feasible and infeasible triples of digits are discussed in Section 4. We consider the properties of admissible suffixes and prefixes in Section 5 before we briefly summarize the known enumeration algorithms in Section 6. A

few preliminary results for base $B = 9$ are given in Appendix A.

2 Computing the sequence of digits of squares

By $a \text{ rem } b$ we denote the remainder of the division of a by b and by $a \text{ div } b$ we abbreviate $\lfloor a/b \rfloor$ whenever $a, b \in \mathbb{N}_{>0}$. With this we have

$$(a \text{ div } b) \cdot b + (a \text{ rem } b) = a.$$

Surely, we all learned in elementary school how to perform long multiplication. So, the following lemma is just a more formal statement settling notation for the case of squaring.

Lemma 1. *Let $B \geq 2$ be a base and $a_0, a_{n-1} \in \{0, \dots, B-1\}$ be arbitrary digits. If*

$$[b_{m-1}, \dots, b_0]_B = \left([a_{n-1}, \dots, a_0]_B \right)^2,$$

then we have

$$b_j = \left(c_{j-1} + \sum_{i=0}^j a_i \cdot a_{j-i} \right) \text{rem } B \quad (2)$$

for all $0 \leq j \leq n-1$, where $c_{-1} := 0$ and

$$c_j := \left(c_{j-1} + \sum_{i=0}^j a_i \cdot a_{j-i} \right) \text{div } B \quad (3)$$

for all $0 \leq j \leq n-1$. For all $n \leq j \leq 2n-2$ we have

$$b_j = \left(c_{j-1} + \sum_{i=j-n+1}^{n-1} a_i \cdot a_{j-i} \right) \text{rem } B, \quad (4)$$

where

$$c_j = \left(c_{j-1} + \sum_{i=j-n+1}^{n-1} a_i \cdot a_{j-i} \right) \text{div } B. \quad (5)$$

For $j = 2n-1$ we have $b_j = c_{j-1}$ and $c_j = 0$.

For the carryovers c_j we have the following bounds.

Lemma 2. *With the notation and conditions from Lemma 1 we have*

$$0 \leq c_j \leq (j+1)B - (j+2) = (j+1)(B-1) - 1 \quad (6)$$

for all $0 \leq j \leq n - 1$ and

$$0 \leq c_{n-1+j} \leq (n - j)B - (n - j) = (n - j)(B - 1) \quad (7)$$

for all $1 \leq j \leq n - 1$.

Proof. For the first part we consider

$$0 \leq \sum_{i=0}^j a_i \cdot a_{j-i} \leq (j + 1)(B - 1)^2,$$

so that, obviously, $c_j \geq 0$ for all $0 \leq j \leq n - 1$ and

$$c_0 = \left\lfloor \left(c_{j-1} + \sum_{i=0}^j a_i \cdot a_{j-i} \right) / B \right\rfloor \leq \lfloor (B - 1)^2 / B \rfloor = B - 2.$$

Using induction we compute

$$c_j = \left\lfloor \left(c_{j-1} + \sum_{i=0}^j a_i \cdot a_{j-i} \right) / B \right\rfloor \leq \lfloor ((j + 1)(B - 1)^2 + jB - j - 1) / B \rfloor = (j + 1)B - (j + 2).$$

The second part can be treated analogously. ■

We remark that $b_{2n-1} \leq B - 1$ can be concluded from Equation (7), reflecting the fact that squaring an n -digit number gives a number with at most $2n$ digits.

Assume that you want to compute just the 189th digit of the square of an 100-digit number. The previous two lemmas can be used to accomplish this task without computing the last 190 digits. More generally, let us assume that we want to compute b_j . To end we start by bounding the carryover $c_{j-\alpha}$, for some suitably large value of α , by $\underline{c}_{j-\alpha} \leq c_{j-\alpha} \leq \bar{c}_{j-\alpha}$. Here we can choose $\underline{c}_{j-\alpha} = 0$ and take $\bar{c}_{j-\alpha}$ according to Lemma 2. Starting from there we can compute the values $\underline{b}_i, \underline{c}_i, \bar{b}_i, \bar{c}_i$ for all $j - \alpha + 1 \leq i \leq j$ according to the formulas in Lemma 1. We can easily check that

$$\bar{c}_i - \underline{c}_i \leq \left\lfloor \frac{\bar{c}_{i-1} - \underline{c}_{i-1}}{B} \right\rfloor, \quad (8)$$

i.e., the estimates for the carryovers c_i are getting better and better. Once we reach $\bar{c}_{i^*} = \underline{c}_{i^*}$, we have $\underline{b}_i = b_i = \bar{b}_i$ for all indices $i > i^*$. While the differences decrease logarithmically in the first steps, they can nevertheless stay at 1 for a long time. As an example consider the computation of the digit b_{24} in

$$123123999999999999^2 = 15159519375999999753752000000000001,$$

where the root consists of $n = 18$ digits. Choosing $\alpha = 7$, we set $\underline{c}_{17} = 0$ and $\bar{c}_{17} = 18 \cdot 9 - 1 = 161$. With this, we compute:

n	18	19	20	21	22	23	24	25	26	27
\underline{b}_n	1	2	9	9	9	9	5	7	3	9
\bar{b}_n	2	8	0	0	0	0	6	7	3	9
\underline{c}_n	62	60	51	42	33	24	19	15	13	8
\bar{c}_n	78	61	52	43	34	25	19	15	13	8

So, even choosing the relatively large value $\alpha = 7$, we only get the information $b_{24} \in \{5, 6\}$. Of course, the long sequence of digits $B - 1$ in the square causes this effect. However, all subsequent digits are computed correctly (and a much smaller value of α would be sufficient to this end).

If $n \leq j < 2n$, then for the computation of b_j choosing $\alpha = \lceil 1 + \log_B(2n - j + 1) \rceil$ is sufficient in most cases, so that $O((2n - j) \log_B(2n - j + 1))$ additions and multiplications for single digits are needed. If j is close to $2n$, then this significantly improves upon the running time $O(n \log n \log \log n)$ of the Schönhage-Strassen algorithm for the multiplication of two n -digit numbers.

However, we will use the recursion from Lemma 1 mainly in the case when $1 \leq j \leq n - 1$. If we assume that c_{j-1} is stored, then we can compute b_j and c_j in $O(j)$ additions and multiplications, which saves us factor of $\log j \log \log j$ at the very least. This can be used if we build up a list of n -digit numbers whose last n digits of the square are contained in some set M from $(n - 1)$ -digit numbers whose last $n - 1$ digits of the square are contained in M , see Section 6.

3 Infinite patterns

In Equation (1) we have given an example of a 1-parametric family of integers whose square consists of the decimal digits 2, 5, and 7 only. Later on we will see examples with more than one parameter. So, by an *infinite pattern* we may understand a function $f: \mathbb{N}^k \rightarrow \mathbb{N}$ such that $f(x)^2$ consists of at most three different digits in a given base B for all $x \in \mathbb{N}^k$ or a suitable infinite subset of \mathbb{N}^k . However, we are not interested in functions f repeating the very same values again and again. Also defining $f(n)$ as the n th number whose square consists of (at most) three different digits is not what we have in mind. So, we are not able to give a precise definition of an “infinite pattern” and leave its meaning at the intuitive level and state examples of certain more structured types in the subsequent subsections. In Subsection 3.1 we consider integers N consisting of some fix prefix, an increasing chain of digits all equal to a fix number $x \neq 0$, and a fix suffix. In Equation (1) the prefix is 1, the repeating digit is $x = 6$, and the suffix is 5. The special case where the repeating digit equals zero is treated in Subsection 3.2. Here we can also have several different blocks of

increasing sequences of zeroes, of the same or different lengths. In the latter case we obtain infinite families with more than one parameter. There are some constructions where a certain pattern is repeated by not just copying but in a more intricate way, see Subsection 3.3. In Subsection 3.4 we summarize our findings and refer to the respective general results from the previous subsections for all known and newly discovered infinite patterns for base $B = 10$ mentioned at <http://www.worldofnumbers.com/threedigits.htm>.

Numbers N such that N^2 contains at most three digits in a given base B and that do not belong to one of the (known) infinite patterns are called *sporadic solutions*. Of course, all $1 \leq N < \sqrt{B^3}$ result in numbers that have at most 3 digits in total. These will also be called *trivial solutions*. For $B \in \{2, 3\}$ the square N^2 of every positive integer N consists of at most three different digits in base B representation. Here we will also speak of trivial solutions and will mainly focus on $B \geq 4$ in the following. For sporadic solutions with many digits we refer to Subsection 3.5.

3.1 Infinite patterns with sequences of non-zero digits

In order to explain our first type of an infinite pattern we first provide a few auxiliary results.

Lemma 3. *Let $B \in \mathbb{N}_{\geq 2}$ and N be a positive integer whose last three digits end with the same integer $0 \leq x \leq B - 1$ in base B representation, i.e., $a_0 = a_1 = a_2 = x$ using the notation from Lemma 1. If the last three digits of N^2 are identical in base B , i.e. $b_0 = b_1 = b_2$, then $x = 0$.*

Proof. We uniquely write $x^2 = aB + b$ with integers $0 \leq a, b \leq B - 1$, so that the last digit of N^2 equals b and the carryover is a . Next we compute

$$2x^2 + a = 2aB + (2b + a),$$

so that using Lemma 1 and its notation yields $b_1 \equiv 2b + a \pmod{B}$. From $b_1 = b$ and $0 \leq a + b \leq 2B - 2$ we then conclude either $a = b = 0$, so that $x = 0$, or

$$a + b = B. \tag{9}$$

In the following we only consider the latter case, where $c_1 = 2a + 1$. With this we compute

$$c_2B + b_2 \stackrel{!}{=} 3x^2 + 2a + 1 = 3aB + 3b + 2a + 1 = (3a + 2)B + (b + 1).$$

Since $b_2 = b$, this is impossible. ■

Note that for $B \geq 5$ it is possible that the last two digits of N in base B are equal to $1 \leq x \leq B - 1$ and also the last two digits of N^2 in base B coincide. A parametric example is given by $x = B - 2$ where N^2 ends with two 4s, e.g., for $B = 10$ we have $[88]^2 = [7744]$.

Lemma 4. Let $B \in \mathbb{N}_{\geq 2}$ and N be a positive integer whose last four digits end with the same integer $0 \leq x \leq B - 1$ in base B representation, i.e., $a_0 = a_1 = a_2 = a_3 = x$. If the last two digits of N^2 are identical in base B and the last but two's digit equals the last but three's digit, i.e. $b_0 = b_1$ and $b_2 = b_3$, then $x = 0$.

Proof. For $B = 2$ either $x = 0$ or $x = 1$. In the latter case $([11]_2)^2$ ends with $[01]_2$, so that we can assume $B \geq 3$ in the following. As in the proof of Lemma 3 we uniquely write $x^2 = aB + b$ and conclude $a + b = B$ if $x \neq 0$. From

$$c_2B + b_2 \stackrel{!}{=} 3x^2 + 2a + 1 = 3aB + 3b + 2a + 1 = (3a + 2)B + (b + 1).$$

we conclude either $b_2 = 0$, $c_2 = 3a + 3$, $b = B - 1$, $a = 1$ or $b_2 = b + 1$, $c_2 = 3a + 2$, $b \leq B - 2$. In the first case we compute

$$c_3B + b_3 \stackrel{!}{=} 4x^2 + 3a + 3 = 4aB + 4b + 3a + 3 = (4a + 3)B + (b + 3) = (4a + 4)B + 2.$$

From $b_3 = b_2 = 0$ we conclude $B = 2$, which is a contradiction. Thus we consider the second case, where

$$c_3B + b_3 \stackrel{!}{=} 4x^2 + 3a + 2 = 4aB + 4b + 3a + 2 = (4a + 3)B + (b + 2).$$

Since $b_3 = b + 1$, this yields a contradiction again. ■

So, if $(\underbrace{[x, \dots, x]_B}_{n \text{ times}})^2$, where $1 \leq x \leq B - 1$ and $n \geq 4$ should contain three subsequent identical digits within its last four digits, then the pattern is of the form $[cccb]_B$, where $c \neq b$. It is indeed possible for general n that the last n digits except the last one are identical:

Lemma 5. Let $B \in \mathbb{N}_{\geq 2}$ and $1 \leq x \leq B - 1$ be an integer such that $x^2 = (B - 1 - b) \cdot B + b$ for a suitable integer b satisfying $1 \leq b \leq B - 1$. Then, we have

$$\left(\underbrace{[x, \dots, x]_B}_{n \text{ times}}\right)^2 = \underbrace{[B - b, \dots, B - b]_B}_{n-1 \text{ times}}, \underbrace{[B - 1 - b, b - 1, \dots, b - 1, b]_B}_{n-1 \text{ times}}$$

for each $n \in \mathbb{N}_{>0}$.

Proof. First we note that $x^2 = (B - 1 - b) \cdot B + b = (B - 1)(B - b)$. The integer N that is squared on the left hand side is given by

$$N = \sum_{i=0}^{n-1} xB^i = x \cdot \frac{B^n - 1}{B - 1},$$

so that

$$N^2 = x^2 \cdot \left(\frac{B^n - 1}{B - 1} \right)^2 = (B - b) \cdot \frac{B^{2n} - 2B^n + 1}{B - 1}.$$

The integer M representing the right hand side is given by

$$\begin{aligned} M &= b + \sum_{i=1}^{n-1} (b-1)B^i + (B-1-b)B^n + \sum_{i=n+1}^{2n-1} (B-b)B^i \\ &= b + (b-1)B \cdot \frac{B^{n-1} - 1}{B-1} + (B-1-b)B^n + (B-b)B^{n+1} \cdot \frac{B^{n-1} - 1}{B-1} \\ &= b + b \cdot \frac{B^n - B}{B-1} - \frac{B^n - B}{B-1} - B^n + (B-b)B^n + (B-b) \cdot \frac{B^{2n} - B^{n+1}}{B-1} \\ &= b \cdot \frac{B^n - 1}{B-1} - B \cdot \frac{B^n - 1}{B-1} + (B-b) \cdot \frac{B^{2n} - B^n}{B-1} \\ &= (B-b) \cdot \frac{B^{2n} - 2B^n + 1}{B-1}, \end{aligned}$$

i.e., $M = N^2$. ■

Next we will see that the condition on the representation of x^2 is not as special as it looks at first sight.

Lemma 6. *Let $B \in \mathbb{N}_{\geq 2}$ and $1 \leq x \leq B-1$ be an integer such that the last n digits in base- B -representation of*

$$\left(\underbrace{[x \dots x]_B}_{n \text{ times}} \right)^2$$

are given by

$$\left[\underbrace{c \dots c}_{n-1 \text{ times}} b \right]_B,$$

where $b, c \in \{0, \dots, B-1\}$ are arbitrary but fixed, for all $n \in \{1, 2, 3\}$. Then, $B-1$ divides x^2 , $b = x^2 \bmod B$, $c = b-1$, $x^2 \operatorname{div} B = B-1-b$, and $b \geq 1$.

Proof. We set $b := x^2 \bmod B$ and $a := x^2 \operatorname{div} B$, so that $a, b \in \{0, \dots, B-1\}$ and

$$x^2 = a \cdot B + b, \tag{10}$$

i.e., we apply the condition on the shape of the digits for $n = 1$. Observe that $a = b = B-1$ is impossible since $x^2 = (B-1)B + (B-1) = B^2 - 1$ has no integral solution x for $B \geq 2$. Thus, we have

$$0 \leq a + b \leq B - 3.$$

Next we apply the condition for $n = 2$ and $n = 3$. Using Lemma 1, including the notation, we have $b_0 = b, b_1 = b_2 = c, c_0 = a$ and we conclude

$$2x^2B + x^2 = 2aB^2 + (a + 2b)B + b, \quad (11)$$

$$3x^2B^2 + 2x^2B + x^2 = 3aB^3 + (2a + 3b)B^2 + (a + 2b)B + b. \quad (12)$$

From Equation (11) and $b_1 = c$ we conclude $a + 2b \equiv c \pmod{B}$. Since $0 \leq a + 2b \leq 3B - 3 < 3B$ and $0 \leq c \leq B - 1$ we have $a + 2b \in \{c, c + B, c + 2B\}$.

- If $a + 2b = c$, then Equation (12) and $b_2 = c$ gives $2a + 3b \equiv c \pmod{B}$. From $a + 2b = c$ we conclude $2a + 3b = c + (a + b) \leq c + (a + 2b) \leq c + c \leq c + (B - 1) < c + B$, so that $2a + 3b = c$ due to $2a + 3b = c + (a + b) \geq c$. Subtracting the equations $a + 2b = c$ and $2a + 3b = c$ yields $a + b = 0$, so that $a, b \geq 0$ gives $a = b = 0$. However, then $x^2 = aB + b = 0$ then implies $x = 0$, which contradicts our assumption $x \geq 1$.
- If $a + 2b = c + 2B$, then Equation (12) and $b_2 = c$ gives $2a + 3b + 2 \equiv c \pmod{B}$. Since $2a + 3b + 2 = (a + 2b) + (a + b + 2) = c + 2B + (a + b + 2)$ we conclude $a + b + 2 \equiv 0 \pmod{B}$. From $0 < a + b + 2 \leq 2B - 1 < 2B$ we conclude $a + b + 2 = B$, so that $a + 2b = c + 2B$ yields $b + B - 2 = c + 2B$, which is equivalent to $b - 2 = c + B$. Since the left hand side is strictly smaller than B and the right hand side is at least B , we obtain a contradiction.

Thus, we have

$$a + 2b = c + B. \quad (13)$$

Equation (12) and $b_2 = c$ gives $2a + 3b + 1 \equiv c \pmod{B}$. Since $2a + 3b + 1 = (a + 2b) + (a + b + 1) = c + 2B + (a + b + 1)$ we conclude $a + b + 1 \equiv 0 \pmod{B}$. Since $0 < a + b + 1 \leq 2B - 2 < 2B$, we have $a + b = B - 1$, so that Equation (13) yields

$$c = b - 1 \quad \text{and} \quad x^2 \operatorname{div} B = a = B - 1 - b.$$

With this we have

$$x^2 = aB + b = (B - 1 - b)B + b = (B - 1)(B - b),$$

so that x^2 is divisible by $B - 1$. Finally, it remains to observe that if $b = 0$, then $a = B - 1$, $x^2 = aB + b = B^2 - B$ and

$$(B - 1)^2 = B^2 - 2B + 1 \stackrel{B \geq 2}{<} x^2 < B^2,$$

which shows that no such integer x exists. ■

Corollary 1. *Let $B \in \mathbb{N}_{\geq 2}$, $n \in \mathbb{N}_{\geq 3}$, and $1 \leq x \leq B - 1$ be an integer such that the last but one and the last but second digit of*

$$\underbrace{([x \dots x]_B)}_{n \text{ times}}^2$$

coincide, then $B - 1$ divides x^2 and the last n digits of the square are given by

$$[\underbrace{c \dots c}_{n-1 \text{ times}} b]_B,$$

where $b = x^2 \bmod B$, $c = b - 1$, $x^2 \operatorname{div} B = B - 1 - b$, and $1 \leq b \leq B - 1$.

From the Lemma 5 and Lemma 6 we directly conclude:

Proposition 1. *Let $B \in \mathbb{N}_{\geq 2}$ and $1 \leq x \leq B - 1$ be an integer such that $B - 1$ divides x^2 . Then, we have*

$$\left(\underbrace{[x, \dots, x]_B}_{n \text{ times}}\right)^2 = \underbrace{[B - b, \dots, B - b, B - 1 - b, b - 1, \dots, b - 1, b]_B}_{n-1 \text{ times}}$$

for each $n \in \mathbb{N}_{>0}$, where $b = x^2 \bmod B$ satisfying $1 \leq b \leq B - 1$.

Note that for $B = 10$ the term $B - 1 = 9$ is a square itself, so that there are $\sqrt{B - 1}$ integers x such that x^2 is divisible by $B - 1$ and $1 \leq x \leq B - 1$. Another example is given by $B = 17$. In general $x = B - 1$ is always a solution leading to

$$\left(\underbrace{[B - 1, \dots, B - 1]_B}_{n \text{ times}}\right)^2 = \underbrace{[B - 1, \dots, B - 1, B - 2, 0, \dots, 0, 1]_B}_{n-1 \text{ times}}$$

If $B - 1$ is *squarefree*¹, then this is indeed the only possibility. Corresponding examples are given by $B = 4$ and $B = 11$. In general there are exactly s solutions where s is the largest integer such that $B - 1 = s^2 t$ for some integer t .

By construction, the squares in Proposition 1 typically consist of four different digits with respect to base B if $n \geq 2$. However, by minor modifications we can achieve three different digits as e.g. shown in Equation (1). In general we assume the form

$$N = s + B^c \cdot x \cdot \frac{B^n - 1}{B - 1} + r \cdot B^{c+n}, \quad (14)$$

where we call r prefix, s suffix, and $c = l_B(s)$ is the number of digits of s in base B . The possible choices for x are completely characterized in Corollary 1. So, we may just loop over all positive integers s, r up to a suitable upper bound, loop over all choices for x , set n to the number of digits of $\max\{s, r\}$, and just check whether N^2 consists of just three different digits. In Table 1 we list the found suitable choices for the three parameters.

As there are suitable suffixes as large as $s = 504485$ we want to go a bit into details of a

¹An integer $n \in \mathbb{N}_{>0}$ is called squarefree if $k^2 | n$ implies $k = 1$ for each positive integer k .

s	r	x	$D_{10}(N^2)$
4		3	{1, 5, 6}
5		3	{1, 2, 5}
5	2	3	{2, 4, 5}
5	123	3	{1, 2, 5}
8		3	{1, 2, 4}
59		3	{1, 2, 8}
504485		3	{1, 2, 5}
5		6	{2, 4, 5}
5	1	6	{2, 5, 7}
7		6	{4, 8, 9}

Table 1: Suitable parameters for Equation (14).

more sophisticated search algorithm. Starting from Equation (14) we compute

$$N^2 = s^2 + 2sxB^c \cdot \frac{B^n - 1}{B - 1} + 2rsB^{c+n} + x^2B^{2c} \cdot \left(\frac{B^n - 1}{B - 1}\right)^2 + 2rxB^{2c+n} \cdot \frac{B^n - 1}{B - 1} + r^2B^{2c+2n}.$$

From here we already see that if c is the number of digits of s , then the last c digits of s^2 occur as digits of N^2 . E.g. for $s = 504485$ the three digits are forced to be contained in $\{1, 2, 5\}$ due to $[504485]^2 = [254505|115225]$. In Section 6 we present an algorithm to compute a list of candidates for s .

Choosing $1 \leq x \leq B - 1$ such that $B - 1$ divides x^2 and setting $b = x^2 \bmod B$ we can rewrite our equation for N^2 to

$$\begin{aligned} N^2 = & (s^2 + bB^{2c}) + (2sx + (b - 1)B^{c+1}) \cdot B^c \cdot \frac{B^{n-1} - 1}{B - 1} + (2sx + 2rsB + (B - 1 - b)B^{c+1}) \cdot B^{c+n-1} \\ & + (2rx + (B - b)B) \cdot B^{2c+n} \cdot \frac{B^{n-1} - 1}{B - 1} + (2rx + r^2B) \cdot B^{2c+2n-1}. \end{aligned} \quad (15)$$

To further bring the formula in the direction of a base- B -representation we need a little auxiliary result.

Lemma 7. *Let $y \in \mathbb{N}_{>0}$ and u, v be defined by $u + (B - 1)v = y$, where $1 \leq u \leq B - 2$ and $v \in \mathbb{N}_{\geq 0}$. With this, let l be the smallest integer such that $u \cdot \frac{B^l - 1}{B - 1} \geq v$. Then, we have*

$$y \cdot \frac{B^n - 1}{B - 1} = \underbrace{u \cdot \frac{B^l - 1}{B - 1}}_{\in [0, B^l - 1]} - v + \sum_{i=0}^{n-l-1} u \cdot B^{l+i} + v \cdot B^n$$

for $n > l$, i.e., the attained digits are contained in $\varphi_B(u \cdot \frac{B^l-1}{B-1} - v)$, $\varphi_B(v)$, or equal to u .

So having chosen s and x we can compute the occurring digits in the last $n + c - 1$ places of N^2 without specifying n . Since $x < B$ we typically have $2rx \ll r^2$, so that the leading digits of N^2 are determined by the leading digits of r^2 . In Section 6 we also present an algorithm to compute a list of candidates for r .

We want to close this subsection by stating a specific parametric choice for r , s , and x .

Lemma 8. *Let $B \geq 2$. If $x := \sqrt{B-1} \in \mathbb{N}$, then $([B-1, \dots, B-1, B-x]_B)^2$ consists of digits in $\{0, B-2x, B-1\}$. If $x := \sqrt{B+1} - 1 \in \mathbb{N}$, then $([B-1, \dots, B-1, B-x]_B)^2$ consists of digits in $\{0, B-2x, B-1\}$.*

Proof. We have $(B^k - x)^2 = B^{2k} - 2x \cdot B^k + x^2$. For $1 \leq x^2 < B$ the digits in base B -representation are given by $0, B-1, B-2x$ and x^2 , so that either $B-1 = x^2$ or $B-2x = x^2$. ■

Is it always, i.e., for all bases B , possible to find a pattern of the form $[B-1, B-1, \dots, B-1, z]_B$ such that the square consists of only three digits? For $B = 10$ we have to choose $z = 7$. For $z = 3$, i.e., the other root of $B-1 = 9$ modulo 10, we end up with squares consisting of four different digits. For e.g. $B = 11$ the number $B-1$ is not a quadratic residue.²

3.2 Infinite patterns with blocks of zeros

If the repeating digit is a zero, then it seems to be much easier to construct some infinite patterns. An easy example is given by:

Lemma 9. *For $B \geq 3$ and $n \geq 0$ we have*

$$\left(\underbrace{[1, 0, \dots, 0, 1]_B}_{n \text{ times}} \right)^2 = \underbrace{[1, 0, \dots, 0, 2, 0, \dots, 0, 1]_B}_{n \text{ times} \quad n \text{ times}}$$

Proof. Let $N \in \mathbb{N}$ be the root on the left hand side, then we have $N = B^{n+1} + 1$. Since the number M on the right hand side is given by $M = B^{2n+2} + 2B^{n+1} + 1$, we have $M = N^2$. ■

There are a lot of similar results with similar proofs (which we omit). Two further examples are given by:

Lemma 10. *For $B \geq 3$ and $n \geq 1$ we have*

$$\left(\underbrace{[1, 0, \dots, 0, 1, 1]_B}_{n \text{ times}} \right)^2 = \underbrace{[1, 0, \dots, 0, 2, 2, 0, \dots, 0, 1, 2, 1]_B}_{n \text{ times} \quad n-1 \text{ times}}$$

²An integer m is called a quadratic residue modulo n , iff there exists an integer x such that $x^2 \equiv m \pmod{n}$.

Lemma 11. For $B \geq 3$ and $n \geq 1$ we have

$$\left([1, 1, \underbrace{0, \dots, 0}_n, 1]_B \right)^2 = [1, 2, 1, \underbrace{0, \dots, 0}_{n-1 \text{ times}}, 0, 2, 2, \underbrace{0, \dots, 0}_n, 1]_B.$$

In order to describe an underlying general construction pattern we use a prefix r and a suffix s .

Lemma 12. Given two positive integers r and s , we have

$$\left([\underbrace{\varphi_B(r), 0, \dots, 0}_n, \varphi_B(s)]_B \right)^2 = [\varphi_B(r^2), \underbrace{0, \dots, 0}_{n+l_B(s)-l_B(2rs)}, \varphi_B(2rs), \underbrace{0, \dots, 0}_{n+l_B(s)-l_B(s^2)}, \varphi_B(s^2)] \quad (16)$$

for all $n \geq \max\{l_B(2rs) - l_B(s), l_B(s^2) - l_B(s)\} = \max\{l_B(2rs), l_B(s^2)\} - l_B(s) \geq 0$.

Proof. The root on the left hand side is given by $N = r \cdot B^{n+l_B(s)} + s$, so that

$$N^2 = r^2 \cdot B^{2n+2l_B(s)} + 2rs \cdot B^{n+l_B(s)} + s^2.$$

■

For the construction of infinite patterns with at most 3 different digits (including zero), where all digits except 0 occur only a finite number of times, we can proceed as follows. Given r and s the condition on the digits of the square is

$$\left| (D_B(r^2) \cup D_B(2rs) \cup D_B(s^2)) \setminus \{0\} \right| \leq 2. \quad (17)$$

So, if we first compute a list of integers s that are not “too large” satisfying $|D_B(s^2) \setminus \{0\}| \leq 2$ than we can check the above condition for all pairs. Note that if there is such a pattern for (r, s) then there is a corresponding “reversed” pattern for (s, r) , so that we assume $r \leq s$ in the subsequent lists. Examples of this construction are given by

- $r = [1]_B, s = [1]_B, r^2 = [1]_B, 2rs = [2]_B, s^2 = [1]_B, D = \{0, 1, 2\}$ for $B \geq 3$;
- $r = [1]_B, s = [1, 1]_B, r^2 = [1]_B, 2rs = [2, 2]_B, s^2 = [1, 2, 1]_B, D = \{0, 1, 2\}$ for $B \geq 3$;
- $r = [1]_B, s = [2]_B, r^2 = [1]_B, 2rs = [4]_B, s^2 = [4]_B, D = \{0, 1, 4\}$ for $B \geq 5$;
- $r = [1]_B, s = [B-1]_B, r^2 = [1]_B, 2rs = [1, B-2]_B, s^2 = [B-2, 1]_B, D = \{0, 1, B-2\}$ for $B \geq 3$;
- $r = [2]_B, s = [2]_B, r^2 = [4]_B, 2rs = [8]_B, s^2 = [4]_B, D = \{0, 4, 8\}$ for $B \geq 9$;
- $r = [2]_B, s = [2, 2]_B, r^2 = [4]_B, 2rs = [8, 8]_B, s^2 = [4, 8, 4]_B, D = \{0, 4, 8\}$ for $B \geq 9$.

We remark that e.g. $r = s = [1, 1]_B$ is not in this list since $r^2 = [1, 2, 1]_B$ and $2rs = [2, 4, 2]_B$. Note that in the above list the examples are valid for all B that are sufficiently large and $\varphi_B(r^2), \varphi_B(2rs), \varphi_B(s^2)$ does not contain the zero digit. A different example is given by $r = [5]_{10}$, $s = [5]_{10}$ with $r^2 = s^2 = [2, 5]_{10}$ and $2rs = [50]_{10}$, so that $D = \{0, 2, 5\}$. We can turn this example into a parametric example:

- $r = [B/2]_B, s = [B/2]_B, r^2 = [(B-2)/4, B/2]_B, 2rs = [B/2, 0]_B, s^2 = [(B-2)/4, B/2]_B, D = \{0, B/2, (B-2)/4\}$ for all bases with $B \equiv 2 \pmod{4}$.

There are also examples where $[r]_B$ or $[s]_B$ contain at least one zero digit:

- $r = [1, 0, 2]_{10}, s = [2, 0, 1]_{10}, r^2 = [1, 0, 4, 0, 4]_{10}, 2rs = [4, 1, 0, 0, 4]_{10}, s^2 = [4, 0, 4, 0, 1]_{10}, D = \{0, 1, 4\}$ for $B = 10$;
- $r = [5]_{10}, s = [5, 0, 5]_{10}, r^2 = [2, 5]_{10}, 2rs = [5, 0, 5, 0]_{10}, s^2 = [2, 5, 5, 0, 2, 5]_{10}, D = \{0, 2, 5\}$ for $B = 10$.

While these two examples work for $B = 10$ only so far, we can generalize them in a different way by inserting more zeros into r and/or s :

- $r = [1, 0, 0, 2]_{10}, s = [2, 0, 0, 1]_{10}, r^2 = [1, 0, 0, 4, 0, 0, 4]_{10}, 2rs = [4, 0, 1, 0, 0, 0, 4]_{10}, s^2 = [4, 0, 0, 4, 0, 0, 1]_{10}, D = \{0, 1, 4\}$ for $B = 10$;
- $r = [1, 0, 0, 0, 2]_{10}, s = [2, 0, 0, 0, 1]_{10}, r^2 = [1, 0, 0, 0, 4, 0, 0, 0, 4]_{10}, 2rs = [4, 0, 0, 1, 0, 0, 0, 0, 4]_{10}, s^2 = [4, 0, 0, 0, 4, 0, 0, 0, 1]_{10}, D = \{0, 1, 4\}$ for $B = 10$;
- $r = [5]_{10}, s = [5, 0, 0, 5]_{10}, r^2 = [2, 5]_{10}, 2rs = [5, 0, 0, 5, 0]_{10}, s^2 = [2, 5, 0, 5, 0, 0, 2, 5]_{10}, D = \{0, 2, 5\}$ for $B = 10$;
- $r = [5]_{10}, s = [5, 0, 0, 0, 5]_{10}, r^2 = [2, 5]_{10}, 2rs = [5, 0, 0, 0, 5, 0]_{10}, s^2 = [2, 5, 0, 0, 5, 0, 0, 0, 2, 5]_{10}, D = \{0, 2, 5\}$ for $B = 10$;
- $r = [5, 0, 5]_{10}, s = [5, 0, 0, 5]_{10}, r^2 = [2, 5, 5, 0, 2, 5]_{10}, 2rs = [5, 0, 5, 5, 0, 5, 0]_{10}, s^2 = [2, 5, 0, 5, 0, 0, 2, 5]_{10}, D = \{0, 2, 5\}$ for $B = 10$.

We remark that these infinite patterns are not listed at <http://www.worldofnumbers.com/threedigits.htm>. Moreover, we can turn the first two examples into a 2-parameter parametric series:

Lemma 13. *Given two integers with $k \geq 1$ and $n \geq k + 1$ we have*

$$\begin{aligned} & \left(\left[\underbrace{1, 0, \dots, 0}_{k \text{ times}}, \underbrace{2, 0, \dots, 0}_{n \text{ times}}, \underbrace{2, 0, \dots, 0, 1}_{k \text{ times}} \right]_{10} \right)^2 \\ = & \left[\underbrace{1, 0, \dots, 0, 4}_{k \text{ times}}, \underbrace{0, 4, 0, \dots, 0, 4}_{k \text{ times}}, \underbrace{0, \dots, 0}_{n-k-1 \text{ times}}, \underbrace{4, 0, \dots, 0, 1}_{k-1 \text{ times}}, \underbrace{0, \dots, 0, 4}_{k+1 \text{ times}}, \underbrace{0, \dots, 0}_{n-k-1 \text{ times}}, \underbrace{4, 0, \dots, 0, 4}_{k \text{ times}}, \underbrace{0, \dots, 0, 1}_{k \text{ times}} \right]_{10} \end{aligned}$$

and

$$\begin{aligned} & \left(\left[\underbrace{2, 0, \dots, 0}_{k \text{ times}}, \underbrace{1, 0, \dots, 0}_{n \text{ times}}, \underbrace{1, 0, \dots, 0}_{k \text{ times}}, 2 \right]_{10} \right)^2 \\ &= \left[\underbrace{4, 0, \dots, 0}_{k \text{ times}}, \underbrace{4, 0, \dots, 0}_{k \text{ times}}, \underbrace{1, 0, \dots, 0}_{n-k-1 \text{ times}}, \underbrace{4, 0, \dots, 0}_{k-1 \text{ times}}, \underbrace{1, 0, \dots, 0}_{k+1 \text{ times}}, \underbrace{0, \dots, 0}_{n-k-1 \text{ times}}, \underbrace{1, 0, \dots, 0}_{k \text{ times}}, \underbrace{4, 0, \dots, 0}_{k \text{ times}}, 4 \right]_{10}, \end{aligned}$$

i.e., the squares consist of the digits 0, 1, and 4 only.

Proof. We set $B := 10$ and apply Lemma 12 with

$$\begin{aligned} r &= B^{k+1} + 2 = \left[\underbrace{1, 0, \dots, 0}_{k \text{ times}}, 2 \right]_B \text{ and} \\ s &= 2 \cdot B^{k+1} + 1 = \left[\underbrace{2, 0, \dots, 0}_{k \text{ times}}, 1 \right]_B, \end{aligned}$$

so that

$$\begin{aligned} r^2 &= B^{2k+2} + 4 \cdot B^{k+1} + 4 = \left[\underbrace{1, 0, \dots, 0}_{k \text{ times}}, \underbrace{4, 0, \dots, 0}_{k \text{ times}}, 4 \right]_B, \\ 2rs &= 4 \cdot B^{2k+2} + 10 \cdot B^{k+1} + 4 = \left[\underbrace{4, 0, \dots, 0}_{k-1 \text{ times}}, \underbrace{1, 0, 0, \dots, 0}_{k \text{ times}}, 4 \right]_{10}, \\ s^2 &= 4 \cdot B^{2k+2} + 4 \cdot B^{k+1} + 1 = \left[\underbrace{4, 0, \dots, 0}_{k \text{ times}}, \underbrace{4, 0, \dots, 0}_{k \text{ times}}, 1 \right]_{B,,} \end{aligned}$$

$$l_B(s) = k + 2, \text{ and } l_B(s^2) = l_B(2rs) = 2k + 3.$$

The second part can be proven analogously, i.e., it arises by interchanging the roles of r and s in Lemma 12. ■

We can slightly generalize Lemma 13:

Lemma 14. *Let*

$$N_1 = \left[\underbrace{1, 0, \dots, 0}_{k \text{ times}}, \underbrace{2, 0, \dots, 0}_{n \text{ times}}, \underbrace{2, 0, \dots, 0}_{k \text{ times}}, 1 \right]_{10} = 1 + 2 \cdot 10^{k+1} + 2 \cdot 10^{n+k+2} + 1 \cdot 10^{n+2k+3}$$

and

$$N_2 = \left[\underbrace{2, 0, \dots, 0}_{k \text{ times}}, \underbrace{1, 0, \dots, 0}_{n \text{ times}}, \underbrace{1, 0, \dots, 0}_{k \text{ times}}, 2 \right]_{10} = 2 + 1 \cdot 10^{k+1} + 1 \cdot 10^{n+k+2} + 2 \cdot 10^{n+2k+3}.$$

Then, N_1^2 and N_2^2 have digits in $\{0, 1, 4\}$ in base 10 if

$$k + n + 2, 2k + 2, 2k + n + 4, 2k + 2n + 4, \text{ and } 3k + n + 4$$

are pairwise different. The conditions are e.g. satisfied if $k > n$.

Proof. We have

$$N_1^2 = 1 + 4 \cdot 10^{k+1} + 4 \cdot 10^{k+n+2} + 4 \cdot 10^{2k+2} + 1 \cdot 10^{2k+n+4} + 4 \cdot 10^{2k+2n+4} + 4 \cdot 10^{3k+n+4} + 4 \cdot 10^{3k+2n+5} + 1 \cdot 10^{4k+2n+6}$$

and

$$N_2^2 = 4 + 4 \cdot 10^{k+1} + 4 \cdot 10^{k+n+2} + 1 \cdot 10^{2k+2} + 1 \cdot 10^{2k+n+4} + 1 \cdot 10^{2k+2n+4} + 4 \cdot 10^{3k+n+4} + 4 \cdot 10^{3k+2n+5} + 4 \cdot 10^{4k+2n+6}.$$

Note that the pairs of exponents that are not mentioned in the statement cannot coincide. ■

The last three examples, before Lemma 13, are part of the following 3-parameter series:

Lemma 15. *Given a basis B with $B \equiv 2 \pmod{4}$ and three integers with $l \geq 1$, $k \geq l + 1$, and $n \geq k + 2$ we have*

$$\begin{aligned} & \left(\left[\underbrace{\frac{B}{2}, 0, \dots, 0}_{k \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_{n \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_{l \text{ times}}, \frac{B}{2} \right]_B \right)^2 \\ &= \left[\underbrace{\frac{B-2}{4}, \frac{B}{2}, 0, \dots, 0}_{k-1 \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_{k \text{ times}}, \underbrace{\frac{B-2}{4}, \frac{B}{2}, 0, \dots, 0}_{n-k-2 \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_{l \text{ times}}, \right. \\ & \quad \left. \underbrace{\frac{B}{2}, 0, \dots, 0}_{k-l-1 \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_{l \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_{n-l-1 \text{ times}}, \underbrace{\frac{B-2}{4}, \frac{B}{2}, 0, \dots, 0}_{l-1 \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_{l \text{ times}}, \frac{B-2}{4}, \frac{B}{2} \right]_{B'} \end{aligned}$$

i.e., the square consists of the digits 0 , $\frac{B-2}{4}$, and $\frac{B}{2}$ only.

Proof. We apply Lemma 12 with

$$\begin{aligned} r &= \frac{B}{2} \cdot B^{k+1} + \frac{B}{2} = \left[\underbrace{\frac{B}{2}, 0, \dots, 0}_{k \text{ times}}, \frac{B}{2} \right]_B \text{ and} \\ s &= \frac{B}{2} \cdot B^{l+1} + \frac{B}{2} = \left[\underbrace{\frac{B}{2}, 0, \dots, 0}_{l \text{ times}}, \frac{B}{2} \right]_B, \end{aligned}$$

so that

$$\begin{aligned}
r^2 &= \frac{B^2}{4} \cdot B^{2k+2} + \frac{B^2}{2} \cdot B^{k+1} + \frac{B^2}{4} = \left[\underbrace{\frac{B-2}{4}, \frac{B}{2}, 0, \dots, 0}_{k-1 \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_k, \frac{B-2}{4}, \frac{B}{2} \right]_B, \\
2rs &= \frac{B^2}{2} \cdot B^{l+k+2} + \frac{B^2}{2} \cdot B^{k+1} + \frac{B^2}{2} \cdot B^{l+1} + \frac{B^2}{2} = \left[\underbrace{\frac{B}{2}, 0, \dots, 0}_l, \underbrace{\frac{B}{2}, 0, \dots, 0}_{k-l-1 \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_l, 0 \right]_B, \\
s^2 &= \frac{B^2}{4} \cdot B^{2l+2} + \frac{B^2}{2} \cdot B^{l+1} + \frac{B^2}{4} = \left[\underbrace{\frac{B-2}{4}, \frac{B}{2}, 0, \dots, 0}_{l-1 \text{ times}}, \underbrace{\frac{B}{2}, 0, \dots, 0}_l, \frac{B-2}{4}, \frac{B}{2} \right]_B,
\end{aligned}$$

$$l_B(s) = l + 2, l_B(s^2) = 2l + 4, \text{ and } l_B(2rs) = l + k + 4. \quad \blacksquare$$

The sequence of Lemma 9, Lemma 10, and Lemma 11, as well as the corollaries from Lemma 12 choosing $r = s = [2]_B$ or $r = [2]_B, s = [2, 2]_B$, are part of a rather general parametric construction. To this end we say that $A = \{a_0, \dots, a_n\}$ is a (finite) *Sidon set*³ iff the pairwise sums $a_i + a_j$ (for $i \leq j$) are all different, i.e., $|\{a_i + a_j : 0 \leq i \leq j \leq n\}| = \binom{n+2}{2}$.

Theorem 1. *Let $A = \{a_0, \dots, a_n\}$ be a non-empty Sidon set, $u \in \mathbb{N}_{\geq 1}$, and $B \in \mathbb{N}$ with $B \geq 2u^2 + 1$. Then, the square of*

$$N = \sum_{i=0}^n u \cdot B^{a_i}$$

consists of digits in $\{0, u^2, 2u^2\}$ in base B .

Proof. We have

$$N^2 = \sum_{i=0}^n u^2 \cdot B^{2a_i} + \sum_{0 \leq i < j \leq n} 2u^2 \cdot B^{a_i + a_j}.$$

Since A is a Sidon set, the exponents of B are pairwise different, so that $1 \leq u^2 < 2u^2 < B$ implies the stated result. \blacksquare

The condition that N is not divisible by B is equivalent to $0 \in A$. Note that <http://www.worldofnumbers.com/threedigits.htm> contains five parametric series of integers N consisting of zeros and twos such that N^2 has base-10 digits contained in $\{0, 4, 8\}$. Four of these patterns consist of three 2s and one of two 2s, i.e.,

$$\left(\underbrace{[2, 0, \dots, 0, 2]_B}_n \right)^2 = \left[\underbrace{4, 0, \dots, 0}_n, \underbrace{8, 0, \dots, 0}_n, 4 \right]_B,$$

³Some authors also speak of *Sidon sequences*. Note that finite Sidon sets are in one-to-one correspondence to Golomb rulers.

where $n \geq 0$. While the latter pattern is exhaustive, the smallest missing example with three 2's is given by

$$([2, 0, 0, 0, 2, 0, 2]_B)^2 = [4, 0, 0, 0, 8, 0, 8, 0, 4, 0, 8, 0, 4]_B$$

for $B \geq 9$ and corresponds to the choice $u = 2$ and $A = \{0, 2, 6\}$ in Theorem 1.⁴ From Lemma 12 it can be obtained choosing $r = [2]_B$ and $s = [2, 0, 2]_B$. However, patterns for $\{0, 1, 2\}$ are in one-to-one correspondence to patterns for $\{0, 4, 8\}$.

Lemma 16. *Let $0 < a < b$ and $s > 1$ be integers such that $bs^2 < B$. Then, we have*

- (1) *If N is a positive integer such that $D_B(N^2) = \{0, a, b\}$, then sN is a positive integer with $D_B((sN)^2) = \{0, as^2, bs^2\}$.*
- (2) *If N is a positive integer such that $D_B(N^2) = \{0, s^2a, s^2b\}$ and s is squarefree, then N/s is a positive integer with $D_B((N/s)^2) = \{0, a, b\}$.*

Proof. For part (1) we write N^2 uniquely as

$$N^2 = \sum_{i=1}^l c_i \cdot B^{n_i} \tag{18}$$

with $0 \leq n_1 < n_2 < \dots < n_l$ and $c_i \in \{a, b\}$ for all $1 \leq i \leq l$. With this we have

$$(sN)^2 = \sum_{i=1}^l (s^2 c_i) \cdot B^{n_i}.$$

For part (2) we observe that all digits as well as B are divisible by s , so that N^2 is divisible by s . Since s is squarefree, also N is divisible by s . With this, we can continue similar as for part (1). ■

While it is rather easy to construct Sidon sets of arbitrary cardinality, take e.g. $A = \{2^0, 2^1, \dots, 2^n\}$, it is a hard and open problem to determine the minimum possible value of $\max\{a \in A\}$ if A has to be a Sidon set of a given cardinality. For “length” $n = \max\{a \in A\} = 6$ the smallest Sidon set has cardinality four and is given by $A = \{0, 1, 4, 6\}$. In our context this leads to

$$([2, 0, 2, 0, 0, 2, 2]_B)^2 = [4, 0, 8, 0, 4, 8, 8, 8, 8, 0, 4, 8, 4]_B$$

for $B \geq 9$. The sequence of the smallest possible lengths per cardinality of the Sidon set is given in <https://oeis.org/A003022> (using the relation to Golomb rulers). See also <https://blogs.distributed.net/2014/02/> for the current state of knowledge.

⁴At www.asahi-net.or.jp/~KC2H-MSM/mathland/math02/math0203.htm under no. 1 and no. 18 patterns are mentioned that may hint to Theorem 1 for $u = 1$ and $u = 2$, respectively. In the first case the description is “uppermost and lowermost digit is 1, and properly arranged 0, 1”.

In order to generalize Lemma 15 we need the following generalization of a Sidon set:⁵

Definition 1. For a positive integer t a set $A = \{a_0, \dots, a_n\}$ is called a t -distance Sidon set if

$$\left| (a_i + a_j) - (a_u + a_v) \right| \geq t$$

for all $0 \leq i \leq j \leq n$ and $0 \leq u \leq v \leq n$ with $(i, j) \neq (u, v)$.

An example of a 2-distance Sidon set with cardinality four is given by $A = \{0, 2, 8, 12\}$. 1-distance Sidon sets are just Sidon sets and from a t -distance Sidon set A we can construct an rt -distance set $rA := \{r \cdot a : a \in A\}$ for every positive integer r .

Theorem 2. Let $A = \{a_0, \dots, a_n\}$ be a non-empty 2-distance Sidon set and $B \in \mathbb{N}_{\geq 1}$ with $B \equiv 0 \pmod{2}$. Then, the square of

$$N = \sum_{i=0}^n \frac{B}{2} \cdot B^{a_i}$$

consists of digits in $\left\{0, \frac{B-2}{4}, \frac{B}{2}\right\}$ in base B if $B \equiv 2 \pmod{4}$.⁶

Proof. We have

$$N^2 = \sum_{i=0}^n \frac{B^2}{4} \cdot B^{2a_i} + \sum_{0 \leq i < j \leq n} \frac{B^2}{2} \cdot B^{a_i + a_j}.$$

Since A is a 2-distance Sidon set, the exponents of B are at pairwise distance at least two, the to-digit numbers $\frac{B^2}{4}$ and $\frac{B^2}{2}$ do not interfere. For $B \equiv 2 \pmod{4}$ we have

$$\frac{B^2}{4} = \frac{B-2}{4} \cdot B + \frac{B}{2}.$$

Additionally we have

$$\frac{B^2}{2} = \frac{B}{2} \cdot B + 0.$$

■

Our 2-distance Sidon set $A = \{0, 2, 8, 12\}$ gives the example

$$\left([5000500000505]_{10} \right)^2 = [25005000255050505000255025]_{10}.$$

Another way to apply Lemma 12 is to choose as parameters r and s expressions that are obtained by applying Lemma 12 to (r_1, s_1) and (r_2, s_2) . As an example we will consider

⁵Other generalizations in the literature consider the situation where the number of solutions of $a_i + a_j = m$ with $i \leq j$ is upper bounded by some constant that may be larger than 1 and/or sums with more summands are considered.

⁶At www.asahi-net.or.jp/~KC2H-MSM/mathland/math02/math0203.htm under no. 15 the case $B = 10$ is adressed. The description is "uppermost and lowermost digit is 5, and properly arranged 0, 5."

$(r_1, s_1) = (r_2, s_2) = (1, 1)$. In both cases we can choose a suitable number n for the length of the block of zeros, where *the* n may be different. So, let us choose the parameterization $r = 1 \cdot B^{k+1} + 1$ and $s = 1 \cdot B^{l+1} + 1$. By construction it is clear that both r^2 and s^2 consist of digits in $\{0, 1, 2\}$ only. So, it remains to check $2rs$, where we compute

$$2rs = 2 \cdot (1 \cdot B^{k+1} + 1) \cdot (1 \cdot B^{l+1} + 1) = 2 \cdot B^{k+l+2} + 2B^{k+1} + 2B^{l+1} + 2.$$

So, if $l \neq k$ and $B \geq 3$, then $2rs$ consists of digits in $\{0, 2\}$ only. For $l = k$ and $B \in \{3, 4\}$ the number $2rs$ consists of digits in $\{0, 1, 2\}$ only. The first case is covered by Theorem 1, while the second is a bit special since it is valid for $B \in \{3, 4\}$ only. For $u > 1$ in Theorem 1 we can also take $l = k$ if $B \in \{2u^2 - 1, 2u^2\}$.

Choosing $((r_1, s_1) = (1, 2)$ and $((r_1, s_1) = (2, 1)$, we end up with Lemma 13 using

$$2 \cdot (1 \cdot B^{k+1} + 2) \cdot (2 \cdot B^{l+1} + 1) = 4 \cdot B^{k+l+2} + 2 \cdot B^{k+1} + 8 \cdot B^{l+1} + 4.$$

Since the digits $\{0, 1, 4\}$ occur anyway, we have to choose $l = k$ and $B \in \{2, 3, 5, 6, 9, 10\}$, so that $10 \bmod B \in \{0, 1, 4\}$, or $B = 4$ with digits in $\{0, 1, 2\}$.

While choosing $r = 1$ and $s = 2$ works in any basis $B \geq 5$, we can choose $r = 1$ and $s = v$ for all $v \geq 3$ and $B \in \{v^2 - 2v, v^2 - 1\}$. Of course, the roles of r and s can be interchanged.

Choosing $(r_1, s_1) = (1, B - 1)$ and $(r_2, s_2) = (B - 1, 1)$ leads to

$$\begin{aligned} & 2 \cdot (1 \cdot B^{k+1} + (B - 1)) \cdot ((B - 1) \cdot B^{l+1} + 1) \\ &= B^{k+l+3} + (B - 2) \cdot B^{k+l+2} + (2B^{k+1} + 2B^{l+3} - 4B^{l+2} + 2B^{l+1}) + 1 \cdot B + (B - 2), \end{aligned}$$

so that the question remains for which k, l and B the term

$$2B^{k+1} + 2B^{l+3} - 4B^{l+2} + 2B^{l+1}$$

has only digits in $\{0, 1, B - 2\}$ in base- B representation. If $B \leq 3$ then we cannot have more than three different digits, so that we assume $B \geq 4$ in the following. If $B = 4$ and $k = l + 2$, then the digit 3 occurs while $B - 2 = 2 \neq 3$. All other cases with $B = 4$ and $k \neq l + 2$ the occurring digits are $\{0, 1, 2\}$. So, we assume $B \geq 5$ in the following. If $k > l + 2$ or $k < l$, then the occurring non-zero digits are given by $\{0, 1, 2, B - 2, B - 4\}$ which has cardinality at least four for $B \geq 5$. If $k = l$, then the occurring non-zero digits are given by $\{0, 1, 4, B - 2, B - 4\}$ which has cardinality at least four for $B \geq 5$. If $k = l + 1$, then the occurring non-zero digits are given by $\{0, 1, 2, 3, B - 2, B - 4\}$ which has cardinality at least four for $B \geq 4$. If $k = l + 1$, then the occurring non-zero digits are given by $\{0, 1, 2, B - 2, B - 4\}$ which has cardinality at least four for $B \geq 5$.

Choosing $(r_1, s_1) = (r_2, s_2) = \left(\frac{B}{2}, \frac{B}{2}\right)$ is covered by Theorem 2.

Of course, Lemma 12 can be generalized to two blocks of zero of length n each

$$\left(\left[\underbrace{[\varphi_B(r), 0, \dots, 0]}_{n \text{ times}}, \underbrace{[\varphi_B(s), 0, \dots, 0]}_{n \text{ times}}, \varphi_B(t) \right]_B \right)^2$$

or l blocks of zero of length n each

$$\left(\left[\underbrace{[\varphi_B(r_0), 0, \dots, 0]}_{n \text{ times}}, \dots, \underbrace{[\varphi_B(r_l), 0, \dots, 0]}_{n \text{ times}} \right]_B \right)^2.$$

We can try something slightly more general for non-negative integers a_0, \dots, a_l and positive integers r_0, \dots, r_l we set

$$N = \sum_{i=0}^l r_i \cdot B^{a_i},$$

so that

$$N^2 = \sum_{i=0}^l r_i^2 \cdot B^{2a_i} + \sum_{0 \leq i < j \leq l} 2r_i r_j \cdot B^{a_i + a_j}.$$

Setting

$$t = \max \{ l_B(r_i^2), l_B(2r_i r_j) : 0 \leq i \leq l, i < j \leq l \}$$

we can choose $A := \{a_0, \dots, a_l\}$ such that A is a t -distance Sidon set. If $D_B(r_i^2) \subseteq D$ for all $0 \leq i \leq l$, $D_B(2r_i r_j) \subseteq D$ for all $0 \leq i < j \leq n$, and $0 \in D$, then we have $D_B(N^2) \subseteq D$ for some subset $D \subseteq \{0, 1, \dots, B-1\}$. Obviously, the conditions are more likely to be satisfied if several of the r_i coincide. While this is a nice general construction strategy, we have to remark that the only known cases with $|A| \geq 3$ where it can be applied satisfy $r_0 = r_1 = \dots = r_l$ and indeed are covered by Theorem 1 and Theorem 2. Having such a general patter for all t -distance Sidon sets A of a given cardinality is maybe too ambitious if $|A| \geq 3$. Another approach is to choose $a_i = i \cdot n + c_i$ for a parameter n and constants $c_0, \dots, c_l \in \mathbb{Z}$. This way the $\binom{l+2}{2}$ terms $r_i^2 \cdot B^{2a_i}$ and $2r_i r_j \cdot B^{a_i + a_j}$ clearly interfere in a base- B representation. However, the r_0, \dots, r_l and the c_0, \dots, c_l might be chosen in such a way that we will find patterns with just two non-zero digits. It is very likely that such pattern will be valid for specific bases only. We want to start to study the situation for $l = 2$ in more detail.

Lemma 17. *Let $B \in \mathbb{N}_{\geq 2}$, $r_0, r_1, r_2 \in \mathbb{N}_{>0}$, $c \in \mathbb{Z}$, $D \subseteq \{0, 1, \dots, B-1\}$ with $0 \in D$, and*

$$N := r_2 \cdot B^{2n+c} + r_1 \cdot B^n + r_0$$

for some integer n . If $D_B(r_2^2) \subseteq D$, $D_B(2r_1 r_2) \subseteq D$, $D_B(2r_1 r_0) \subseteq D$, $D_B(r_0^2) \subseteq D$, and $D_B(2r_0 r_2 \cdot B^c +$

$r_1^2) \subseteq D$ (if $c \geq 0$) or $D_B(2r_0r_2 + r_1^2 \cdot B^{-c}) \subseteq D$ (if $c \leq 0$), then we have $D_B(N^2) \subseteq D$ for all

$$n \geq \max\{l_B(r_0^2), l_B(2r_1r_0) - c, l_B(2r_0r_2 + r_1^2B^{-c}) - c, l_B(2r_1r_2) - c\} \quad (19)$$

if $c \leq 0$ and

$$n \geq \max\{l_B(r_0^2), l_B(2r_1r_0), l_B(2r_0r_2B^c + r_1^2) - c, l_B(2r_1r_2) - c\} \quad (20)$$

if $c \geq 0$.

Proof. We compute

$$N^2 = r_2^2 \cdot B^{4n+2c} + 2r_1r_2 \cdot B^{3n+c} + (2r_0r_2B^c + r_1^2) \cdot B^{2n} + 2r_1r_0 \cdot B^n + r_0^2.$$

If n is at least as large as requested, then the terms before the powers of B do not interfere in base- B representation. ■

Below we give some examples for the application of Lemma 17:

- (1) $r_0 = r_2 = 1, r_1 = 3, c = 0, D = \{0, 1, 6\}$ for $n \geq 2$ and $B \in \{5, 6, 10, 11\}$ (for $B = 5$ we need $n \geq 3$ and have $D = \{0, 1, 2\}$; for $B = 6$ we have $B \in \{0, 1, 5\}$);
- (2) $r_0 = r_2 = 1, r_1 = 8, c = 0, D = \{0, 1, 6\}$ for $n \geq 2$ and $B \in \{4, 8, 10, 50, 65, 66\}$ (for $B \in \{50, 65, 66\}$ we have $D = \{0, 1, 16\}$; or $B \in \{4, 8\}$ we have $D = \{0, 1, 2\}$, where for $B = 4$ we need $n \geq 3$);
- (3) $r_0 = r_2 = 1, r_1 = 4, c = 0, D = \{0, 1, 8\}$ for $n \geq 2$ and $B \in \{4, 5, 8, 10, 17, 18\}$ (for $B \in \{4, 8\}$ we have $D = \{0, 1, 2\}$ and for $B = 5$ we have $D = \{0, 1, 3\}$);
- (4) $r_0 = r_2 = 1, r_1 = 9, c = 1, D = \{0, 1, 8\}$ for $n \geq 2$ and $B \in \{4, 5, 9, 10\}$ (for $B \in \{4, 9\}$ we have $D = \{0, 1, 2\}$ and for $B = 5$ we have $D = \{0, 1, 3\}$);
- (5) $r_0 = r_2 = 2, r_1 = 6, c = 0, D = \{0, 2, 4\}$ for $n \geq 2$ and $B \in \{10, 11\}$;
- (6) $r_0 = r_2 = 2, r_1 = 1, c = 0, D = \{0, 4, 9\}$ for $n \geq 1$ and $B \geq 8$ or $B \in \{4, 5\}$ (for $B \in \{5, 8, 9\}$ we have $D = \{0, 1, 4\}$ and for $B = 4$ we have $D = \{0, 1, 2\}$);
- (7) $r_0 = r_2 = 4, r_1 = 127, c = 0, D = \{0, 1, 6\}$ for $n \geq 5$ and $B = 10$;
- (8) $r_0 = r_2 = 8, r_1 = 254, c = 0, D = \{0, 4, 6\}$ for $n \geq 5$ and $B = 10$;
- (9) $r_0 = r_2 = 15, r_1 = 85, c = 2, D = \{0, 2, 5\}$ for $n \geq 4$ and $B = 10$.

Looking at the cases (1)-(4) we might look at the parametric case $r_0 = r_2 = 1, r_1 = x$, and $c = 0$. Here we have $\{0, 1\} \subseteq D$ and the remaining digit is determined by the base B -representation of $2x$ and $2 + x^2$. If $B > 2x$, then we have the possibilities $B \in \{x^2 - 2x + 2, x^2 + 1, x^2 + 2\}$, which gives $x \in \{3, 4\}$ for $B = 10$. For $x < B \leq 2B$ we can perform similar computations and obtain the solution $x = B + 1 - \sqrt{B - 1}$ if $B - 1$ is a square. If $|c|$ is sufficiently large, then the digits of

$2r_0r_2B^c + r_1^2$ are given by the digits of $2r_0r_2$ and r_1^2 , i.e. $D = \{0, 1, 2\}$ and r_1^2 has to consist of digits in $\{0, 1, 2\}$. Clearly we can choose $r_1 = 1$, but then the situation is covered by Theorem 1.

The parameters of e.g. case (9) look a bit *sporadic* so that the question arises who we can algorithmically find those cases for a given base $B \geq 4$:

Step 1 Compute a list/set L of positive integers M such that $|D_B(M^2) \setminus \{0\}| \leq 2$.

Step 2 Loop over all $r_0, r_2 \in L$ with $|(D_B(r_0^2) \cup D_B(r_2^2)) \setminus \{0\}| \leq 2$. Set $D := D_B(r_0^2) \cup D_B(r_2^2) \cup \{0\}$.

Step 3 Compute a list/set L' of positive integers r_1 such that r_1^2 consists of digits in D in base B -representation except for a sequence of consecutive digits of length at most $l_B(2r_0r_2) + 1$.

Step 4 Loop over all $c \in \mathbb{Z}$ with $|c| \leq l_B(2r_0r_2) + 1$ and all $r_1 \in L'$. Check whether

$$D_B\left(\left(2r_0r_2B^c + r_1^2\right) \cdot B^{\max\{0, -c\}}\right) \subseteq D$$

and eventually output the parameters.

We remark that so far all found examples satisfy $r_0 = r_2$. While the presented technique is in principle applicable for $l \geq 3$ blocks of zeros of roughly length n , we have not found such an example that is not covered by the construction using t -distance Sidon sets, i.e., where the blocks all have lengths in terms of pairwise different parameters (modulo some constraints).

For base $B = 10$ and $D = \{0, 1, 2\}$ another, so far unknown,⁷ infinite pattern can be constructed. To this end let us consider the ansatz

$$N = 4 \cdot 10^x + \sum_{i=0}^l 10^{n_i} \tag{21}$$

for some integers x and $0 = n_0 < n_1 < \dots < n_l$, so that

$$N^2 = \sum_{i=0}^l 10^{2n_i} + \sum_{0 \leq i < j \leq l} 2 \cdot 10^{n_i+n_j} + \sum_{i=0}^l 8 \cdot 10^{x+n_i} + 16 \cdot 10^{2x}. \tag{22}$$

It is easy to see that digits 0, 1, and 2 will occur, so that we need to get rid of the terms with multipliers 8 and 16. Since $8 + 2 = 10$ and $16 + 2 \cdot 2 = 20$, the idea is to choose x and the n_i in such a way that there exist indices $a_{i,1}, a_{i,2}$ with $x + n_i = n_{a_{i,1}} + n_{a_{i,2}}$ for $0 \leq i \leq l$ and two different additional solutions of $2x = n_{i'} + n_{j'}$ for suitable indices $0 \leq i', j' \leq l$. For $l = 5$ an example is given by $x + n_0 = n_1 + n_2$, $x + n_1 = n_0 + n_3$, $x + n_2 = n_0 + n_4$, $x + n_3 = n_1 + n_5$, $x + n_4 = n_2 + n_5$, $x + n_5 = n_3 + n_4$, and $2x = n_0 + n_5 = n_1 + n_4$, where $n_0 = 0$. Solving the

⁷At www.asahi-net.or.jp/~KC2H-MSM/mathland/math02/math0203.htm under no. 2 some examples of the discussed type are listed. The description is "numbers of 0s between 1 and 1, and 1 and 4 is an odd number". However, we e.g. have $1010000010004000100000101^2 = 1020100020208080302080222020802030808020200010201$.

corresponding equation system gives a 2-parameter solution. It remains to ensure that the exponents of the remaining terms are pairwise different.

Lemma 18. *Let $1 \leq n_1 < n_2$ be integers, $n_0 = 0$, $n_3 = 2n_1 + n_2$, $n_4 = n_1 + 2n_2$, $n_5 = 2n_1 + 2n_2$, $x = n_1 + n_2$, and*

$$N = 4 \cdot 10^x + \sum_{i=0}^5 10^{n_i}. \quad (23)$$

If $0, n_1, 2n_1, 1 + n_1 + n_2, 1 + 2n_1 + n_2, 3n_1 + n_2, 2n_2, 1 + n_1 + 2n_2, 2n_1 + 2n_2, 1 + 2n_1 + 2n_2, 1 + 3n_1 + 2n_2, 4n_1 + 2n_2, n_1 + 3n_2, 1 + 2n_1 + 3n_2, 1 + 3n_1 + 3n_2, 4n_1 + 3n_2, 2n_1 + 4n_2, 3n_1 + 4n_2$, and $4n_1 + 4n_2$ are pairwise different integers, the N^2 contains only the digits 0, 1, and 2 in base 10. This condition is e.g. satisfied for $n_1 \geq 2, n_2 \geq 3n_1 + 1$.

Proof. We compute

$$\begin{aligned} N^2 = & 1 + 2 \cdot 10^{3n_1+n_2} + 10^{4n_1+4n_2} + 22 \cdot 10^{2n_1+2n_2} + 10^{1+n_1+2n_2} + 10^{1+2n_1+n_2} + 2 \cdot 10^{3n_1+4n_2} \\ & + 2 \cdot 10^{4n_1+3n_2} + 10^{1+3n_1+3n_2} + 10^{1+2n_1+3n_2} + 10^{1+3n_1+2n_2} + 10^{2n_1+4n_2} + 2 \cdot 10^{n_1+3n_2} \\ & + 10^{4n_1+2n_2} + 10^{2n_2} + 10^{2n_1} + 2 \cdot 10^{n_1} + 2 \cdot 10^{n_2} + 10^{1+n_1+n_2}. \end{aligned}$$

■

The number of occurring ones in the base 10-representation of N^2 is 12 and the number of occurring twos is 8. An example is given by $(n_1, n_2) = (2, 7)$, i.e.,

$$([1010000104010000101]_{10})^2 = [1020100210100211022100121010020010201]_{10}.$$

We remark that also other pairs (n_1, n_2) , violating $n_2 \geq 3n_1 + 1$, satisfy the condition on the pairwise different exponents in Lemma 18. Examples are e.g. given by $(3, 8)$, $(4, 6)$, $(4, 10)$, $(4, 11)$, $(5, 7)$, $(5, 8)$, $(5, 12)$, $(5, 13)$, and $(5, 14)$.

Actually, Lemma 18 is just an instance of the more general idea outlined before and the question arises if more such results can be found. We remark that this is impossible if $l \leq 3$. However, we conjecture that for all $l \geq 5$ such patterns can be found.

3.3 “Intricate” patterns

A very interesting type of patterns found by the Iranian mathematician Farideh Firoozbakht (1962–2019) are so called “intricate” patterns, c.f.

<http://www.worldofnumbers.com/threedigits.htm>.

As a shorthand notation we write $\langle a'_1, \dots, a'_l \rangle$ for

$$\underbrace{49 \dots 949}_{a'_1 \text{ times}} \dots \underbrace{9}_{a'_2 \text{ times}} \dots \underbrace{49 \dots 95}_{a'_l \text{ times}},$$

where the a'_i are non-negative integers. Only sum choice lead numbers N with $D_{10}(N^2) \subseteq \{0, 2, 5\}$. Examples are e.g. given by $\langle 0 \rangle$, $\langle 0, 1 \rangle$, $\langle 0, 1, 3 \rangle$, $\langle 0, 1, 3, 7 \rangle$, $\langle 0, 1, 3, 7, 15 \rangle$, \dots . A few more irregular such examples are known and described parametrically. However, examples as e.g. $\langle 0, 1, 3, 2, 10 \rangle$ and $\langle 0, 1, 3, 2, 4, 9 \rangle$ were unknown so far. The question arises for which (finite) sequences a'_i we end up with a square consisting of digits in $\{0, 2, 5\}$. To this end we introduce a different representation. Let a_1, \dots, a_l be pairwise different positive integers and

$$N := \sum_{i=1}^l (5 \cdot 10^{a_i} - 10^{a_{i+1}+1}) + 5, \quad (24)$$

where $a_{l+1} := 0$. For $(a_1, a_2, a_3) = (7, 6, 4)$ we have $N = 44949995$ and $N^2 = 2020502050500025$. We can easily convert a sequence a_1, a_2, \dots, a_l with $a_1 > a_2 > \dots > a_l > 0$ to a representation $\langle a'_1, \dots, a'_l \rangle$ and vice versa:

$$a_i = \sum_{j=i}^l a'_j + (l - i + 1) \quad (25)$$

and

$$a'_i = a_i - a_{i+1} - 1 \quad (26)$$

for all $1 \leq i \leq l$, where we set $a_{l+1} = 0$. Next we evaluate and simplify the expression for N^2 , when N is given as specified in Equation (24), in terms of the a_i for small values of l :

$$\begin{aligned} N^2 &= 25 \cdot 10^{2a_1} + 25 - 5 \cdot 10^{a_1+1} \\ N^2 &= 25 \cdot 10^{2a_1} + 25 \cdot 10^{2a_2} + 25 - 5 \cdot 10^{a_1+a_2+1} - 5 \cdot 10^{a_1+1} + 5 \cdot 10^{a_2+1} \\ N^2 &= 25 \cdot 10^{2a_1} + 25 \cdot 10^{2a_2} + 25 \cdot 10^{2a_3} + 25 - 5 \cdot 10^{a_1+a_2+1} - 5 \cdot 10^{a_1+a_3+1} - 5 \cdot 10^{a_1+1} \\ &\quad + 5 \cdot 10^{a_2+a_3+1} + 5 \cdot 10^{a_2+1} + 5 \cdot 10^{a_3+1} \\ N^2 &= 25 \cdot 10^{2a_1} + 25 \cdot 10^{2a_2} + 25 \cdot 10^{2a_3} + 25 \cdot 10^{2a_4} + 25 \\ &\quad - 5 \cdot 10^{a_1+a_2+1} - 5 \cdot 10^{a_1+a_3+1} - 5 \cdot 10^{a_1+a_4+1} - 5 \cdot 10^{a_1+1} \\ &\quad + 5 \cdot 10^{a_2+a_3+1} + 5 \cdot 10^{a_2+a_4+1} + 5 \cdot 10^{a_3+a_4+1} + 5 \cdot 10^{a_2+1} + 5 \cdot 10^{a_3+1} + 5 \cdot 10^{a_4+1} \end{aligned}$$

Since we only want to use the digits in $\{0, 2, 5\}$ the terms with a “-5”-coefficient have to cancel out by a suitable choice of the a_i . W.l.o.g. we assume $a_1 > a_2 > \dots > a_l$. For $l = 1$ we need $2a_1 = a_1 + 1$, so that $a_1 = 1$, $N = 45$, and $N^2 = 2025$. For $l = 2$ the ordering of the $a_1 > a_2$ forces the cancellation given by $2a_1 = a_1 + a_2 + 1$, i.e. $a_2 = a_1 - 1$. Since $a_1 + 1 > a_2 + 1$ and $a_1 + 1 > 0$,

we also need $2a_2 = a_1 + 1$, so that $a_1 = 3$, $a_2 = 2$, $N = 4495$, and $N^2 = 20205025$. For $l = 3$, choosing $2a_1 = a_1 + a_2 + 1$, $2a_2 = a_1 + a_3 + 1$, and $2a_3 = a_1 + 1$ yields the unique solution $a_1 = 7$, $a_2 = 6$, $a_3 = 4$ leading to $N = 44949995$ and $N^2 = 2020502050500025$. In general we have

$$N^2 = \sum_{i=1}^l 25 \cdot 10^{2a_i} + 25 - \sum_{i=2}^l 5 \cdot 10^{a_1+a_i+1} - 5 \cdot 10^{a_1+1} + \sum_{2 \leq i < j \leq l} 5 \cdot 10^{a_i+a_j+1} + \sum_{i=2}^l 5 \cdot 10^{a_i+1}. \quad (27)$$

For larger l there are several possibilities to match the “-5”-exponents with the “+25”- or “+5”-exponents. The choice $2a_i = a_1 + a_{i+1} + 1$ for $1 \leq i \leq l-1$ and $2a_l = a_1 + 1$ leads to $a_i = 2^l - 2^{i-1}$ for all $1 \leq i \leq l$. It can be easily check that the remaining 2s and 5s do not interfere.

In the remaining part we return to the $\langle a'_1, \dots, a'_l \rangle$ -notation again. As mentioned, we have just one possibility for each l with $1 \leq l \leq 3$, i.e., $\langle 0 \rangle$, $\langle 0, 1 \rangle$, and $\langle 0, 1, 3 \rangle$. For $l = 4$ we have the two solutions $\langle 0, 1, 3, 7 \rangle$ and $\langle 0, 1, 3, 2 \rangle$ (or equivalently $15, 14, 12, 8$ and $10, 9, 7, 3$). Let us denote the number of solutions by β_l . From computer searches we know $\beta_1 = 1$, $\beta_2 = 1$, $\beta_3 = 1$, $\beta_4 \geq 2$, $\beta_5 \geq 5$, $\beta_7 \geq 40$, and $\beta_8 \geq 125$.

- $l = 5$: $\langle 0, 1, 3, 2, 4 \rangle, \langle 0, 1, 3, 2, 10 \rangle, \langle 0, 1, 3, 7, 2 \rangle, \langle 0, 1, 3, 7, 6 \rangle, \langle 0, 1, 3, 7, 15 \rangle$;
- $l = 6$: $\langle 0, 1, 3, 2, 4, 9 \rangle, \langle 0, 1, 3, 2, 4, 15 \rangle, \langle 0, 1, 3, 2, 10, 9 \rangle, \langle 0, 1, 3, 2, 10, 21 \rangle, \langle 0, 1, 3, 7, 2, 6 \rangle, \langle 0, 1, 3, 7, 2, 12 \rangle, \langle 0, 1, 3, 7, 2, 18 \rangle, \langle 0, 1, 3, 7, 6, 2 \rangle, \langle 0, 1, 3, 7, 6, 8 \rangle, \langle 0, 1, 3, 7, 6, 22 \rangle, \langle 0, 1, 3, 7, 15, 2 \rangle, \langle 0, 1, 3, 7, 15, 6 \rangle, \langle 0, 1, 3, 7, 15, 14 \rangle, \langle 0, 1, 3, 7, 15, 31 \rangle$;
- $l = 7$: $\langle 0, 1, 3, 2, 4, 9, 25 \rangle, \langle 0, 1, 3, 2, 4, 15, 9 \rangle, \langle 0, 1, 3, 2, 4, 15, 14 \rangle, \langle 0, 1, 3, 2, 4, 15, 31 \rangle, \langle 0, 1, 3, 2, 10, 9, 11 \rangle, \langle 0, 1, 3, 2, 10, 9, 31 \rangle, \langle 0, 1, 3, 2, 10, 21, 9 \rangle, \langle 0, 1, 3, 2, 10, 21, 20 \rangle, \langle 0, 1, 3, 2, 10, 21, 43 \rangle, \langle 0, 1, 3, 7, 2, 6, 25 \rangle, \langle 0, 1, 3, 7, 2, 12, 6 \rangle, \langle 0, 1, 3, 7, 2, 12, 17 \rangle, \langle 0, 1, 3, 7, 2, 12, 31 \rangle, \langle 0, 1, 3, 7, 2, 18, 6 \rangle, \langle 0, 1, 3, 7, 2, 18, 17 \rangle, \langle 0, 1, 3, 7, 2, 18, 37 \rangle, \langle 0, 1, 3, 7, 6, 2, 19 \rangle, \langle 0, 1, 3, 7, 6, 2, 25 \rangle, \langle 0, 1, 3, 7, 6, 8, 21 \rangle, \langle 0, 1, 3, 7, 6, 8, 31 \rangle, \langle 0, 1, 3, 7, 6, 22, 2 \rangle, \langle 0, 1, 3, 7, 6, 22, 21 \rangle, \langle 0, 1, 3, 7, 6, 22, 45 \rangle, \langle 0, 1, 3, 7, 15, 2, 6 \rangle, \langle 0, 1, 3, 7, 15, 2, 14 \rangle, \langle 0, 1, 3, 7, 15, 2, 28 \rangle, \langle 0, 1, 3, 7, 15, 2, 34 \rangle, \langle 0, 1, 3, 7, 15, 6, 2 \rangle, \langle 0, 1, 3, 7, 15, 6, 14 \rangle, \langle 0, 1, 3, 7, 15, 6, 24 \rangle, \langle 0, 1, 3, 7, 15, 6, 38 \rangle, \langle 0, 1, 3, 7, 15, 14, 2 \rangle, \langle 0, 1, 3, 7, 15, 14, 6 \rangle, \langle 0, 1, 3, 7, 15, 14, 16 \rangle, \langle 0, 1, 3, 7, 15, 14, 46 \rangle, \langle 0, 1, 3, 7, 15, 31, 2 \rangle, \langle 0, 1, 3, 7, 15, 31, 6 \rangle, \langle 0, 1, 3, 7, 15, 31, 14 \rangle, \langle 0, 1, 3, 7, 15, 31, 30 \rangle, \langle 0, 1, 3, 7, 15, 31, 63 \rangle$.

A first step into an understanding of the possible solutions might be:

Conjecture 1. *If $\langle a'_1, \dots, a'_l \rangle$ is a solution with $l \geq 2$, then $\langle a'_1, \dots, a'_{l-1} \rangle$ is also a solution.*

We remark that we can generalize Equation (24)

$$N := \sum_{i=1}^l \left(\frac{B}{2} \cdot B^{a_i} - B^{a_i+1} \right) + \frac{B}{2}. \quad (28)$$

For all mentioned examples $\langle a'_1, \dots, a'_l \rangle$ the square of the corresponding integer only consists of digits in base B in $\{0, \frac{B}{2}, \frac{B-2}{4}\}$ if $B \equiv 2 \pmod{4}$ and $B > 2$.

Table 2: Explanations for the known infinite patterns in base $B = 10$.

There are also some patterns that are quite similar but do not fit directly in the previously described family of patterns.

Proposition 2. *Let $B \equiv 2 \pmod{4}$ with $B \geq 4$ and*

$$N = \frac{B}{2} + \frac{B}{2} \cdot B^2 + \frac{B}{2} \cdot B^3 + B^4 \cdot \left(\frac{B}{2} \cdot B^3 - 1 \right) + \frac{B}{2} \cdot B^{10} + \sum_{i=0}^l \frac{B}{2} \cdot B^{10+6 \cdot 2^i}. \quad (29)$$

For each $l \in \mathbb{Z}$ we have $\varphi_B(N^2) = \left\{ 0, \frac{B}{2}, \frac{B-2}{4} \right\}$.

Proof. Using the abbreviation $u = \frac{B}{2}$ we compute

$$\begin{aligned} N^2 &= u^2 + u \cdot B^3 + (u^2 - u) \cdot B^4 + (u^2 - u) \cdot B^6 + u \cdot B^8 + u \cdot B^{10} + u \cdot B^{13} + (u^2 - u) \cdot B^{14} \\ &\quad + u \cdot B^{18} + u^2 \cdot B^{20} + \sum_{i=0}^l u^2 B^{20+12 \cdot 2^i} + \sum_{0 \leq i < j \leq l} u \cdot B^{21+6 \cdot 2^i+6 \cdot 2^j} \\ &\quad + \sum_{i=0}^l \left(u \cdot B^{11+6 \cdot 2^i} + u \cdot B^{13+6 \cdot 2^i} - u \cdot B^{14+6 \cdot 2^i} + u \cdot B^{18+6 \cdot 2^i} + u \cdot B^{21+6 \cdot 2^i} \right) \\ &= u^2 + u \cdot B^3 + (u^2 - u) \cdot B^4 + (u^2 - u) \cdot B^6 + u \cdot B^8 + u \cdot B^{10} + u \cdot B^{13} + (u^2 - u) \cdot B^{14} \\ &\quad + u \cdot B^{18} + u^2 \cdot B^{20+6 \cdot 2^{l+1}} + \sum_{0 \leq i < j \leq l} u \cdot B^{21+6 \cdot 2^i+6 \cdot 2^j} \\ &\quad + \sum_{i=0}^l \left(u \cdot B^{11+6 \cdot 2^i} + u \cdot B^{13+6 \cdot 2^i} + (u^2 - u) \cdot B^{14+6 \cdot 2^i} + u \cdot B^{18+6 \cdot 2^i} + u \cdot B^{21+6 \cdot 2^i} \right). \end{aligned}$$

Noting that $u = \frac{B}{2}$, $u^2 - u = \frac{B-2}{4} \cdot B$, and $u^2 = \frac{B-2}{4} \cdot B + \frac{B}{2}$, it remains to observe that the exponents $0, 1, 3, 4, 5, 6, 7, 8, 10, 13, 14, 15, 18, \{20, 21\} + 6 \cdot 2^{l+1}, \{11, 13, 14, 15, 18, 21\} + 6 \cdot 2^i$ for $0 \leq i \leq l$, and $21 + 6 \cdot 2^i + 6 \cdot 2^j$ for $0 \leq i < j \leq l$ of the occurring non-zero digits are pairwise different. ■

Examples for $B = 10$ are given by

$$\begin{aligned} 50049995505^2 &= 2505002050050520205025, \\ 50000050049995505^2 &= 2500005005002055502050050520205025, \text{ and} \\ 5000000000050000050049995505^2 &= 250000000005000005005002050505005002055502050050520205025. \end{aligned}$$

The following three examples might also be part of an infinite pattern:

$$\begin{aligned} 50000004999999955050005^2 &= 2500000500000020505000050500052020502050500025, \\ 5005000000499999999955050005^2 &= 2505002500500500000020500505500050500050002020502050500025, \text{ and} \\ 5000000500499999999955050005^2 &= 2500000500500025050020505000050050550050002020502050500025. \end{aligned}$$

3.4 Summary

The idea of this subsection is to summarize our known knowledge on the infinite patterns for base $B = 10$. In Table 2 we list the known patterns mentioned at www.worldofnumbers.com/threedigits.htm, excluding those that are discussed in Subsection 3.3, and a few new ones. In all cases we give a reference to a more general result. Theorem 1 with $u \in \{1, 2\}$, Theorem 2, and Lemma 18 give further patterns not mentioned in the table. Due to the relation between examples with decimal digits in $\{0, 1, 2\}$ and those with decimal digits in $\{0, 4, 8\}$, see Lemma 16, we have dropped the patterns for the latter.

3.5 Sporadic solutions

Let $D \subseteq \{0, \dots, 9\}$ be a set of three decimal digits. All integers N with $D_{10}(N^2) = D$ that are not contained in one of the constructions of the previous subsections are called *sporadic solutions*. Of course it can happen that a new general construction is discovered so that some sporadic solutions may lose this label in the future. Hisanori Mishima has tabulated all sporadic solutions for the case $0 \in D$ for all $N \leq 10^{23}$ and for the case $0 \notin D$ for all $N \leq 10^{25}$, see www.asahi-net.or.jp/~KC2H-MSM/mathland/math02/math0210.htm. We state a few newly discovered sporadic solutions in Table 3.

Table 3: Sporadic solutions N with $|D_{10}(N^2)| = 3$ and many digits

4 Feasible and infeasible triples of digits

Given a base $B \geq 2$ and a set $D \subseteq \{0, 1, \dots, B - 1\}$ of cardinality 3, does there exist a positive integer N , not divisible by B , such that $D_B(N^2) = D$? For the positive answer, where we call D *feasible*, it is sufficient to provide an example. For the negative answer, where we call D

infeasible, we have the following rather easy kind of certificate, which we want to explain in terms of an example. Consider the set

$$\begin{aligned} & \{n^2 \bmod 100 : 1 \leq n \leq 99, n \not\equiv 0 \pmod{10}\} \\ &= \{1, 4, 9, 16, 21, 24, 25, 29, 36, 41, 44, 49, 56, 61, 64, 69, 76, 81, 84, 89, 96\}. \end{aligned}$$

With this we can easily check that e.g. $D = \{0, 2, 8\}$ is infeasible since none of the nine combinations of two digits in D occurs in the above set. Of course, we can also consider the last three or last four digits of N^2 . For bases $B \in \{9, 10\}$ we remark that the last two digits are sufficient, i.e., the infeasible patterns are characterized by the non-existence of 2-suffixes, see Section 5.

As a more general statement we observe that each D not containing an even number is infeasible, i.e., not all digits can be odd.

Lemma 19. *Let $B \in \mathbb{N}_{\geq 2}$ and $N \in \mathbb{N}$ such that $l_B(N^2) \geq 2$. If $B \equiv 2 \pmod{4}$, then $D_B(N^2)$ contains an even element, i.e., N^2 contains an even digit in base B -representation.*

Proof. Let us write $[a_1, a_0]_B$ for the last two digits of N and $[b_1, b_0]_B$ for the last two digits of N^2 . If $2|N$, then $2|b_0$, i.e., b_0 is even. Thus, we assume $a_0 = 2k + 1$ for some integer $0 \leq k \leq B/2 - 1$. Now we consider

$$b_1 \cdot B + b_0 \equiv 2a_0a_1 \cdot B + a_0^2 \equiv 2a_0a_1 \cdot B + 4k^2 + 4k + 1 \pmod{B^2},$$

which implies

$$b_1 \equiv 2a_0a_1 + (4k^2 + 4k + 1) \operatorname{div} B \pmod{B}.$$

Since B is even we have $(4k^2 + 4k + 1) \operatorname{div} B = (4k(k + 1)) \operatorname{div} B$, so that $2a_0a_1 \equiv 0 \pmod{2}$ and $B \not\equiv 0 \pmod{4}$ imply $b_1 \equiv 0 \pmod{2}$, i.e., b_1 is even. ■

Surely, there are $\binom{B}{3}$ possible triples for base B . The two undecided triples for $B = 10$ are given by $\{0, 1, 3\}$ and $\{6, 7, 8\}$. We remark that for the triple $\{5, 6, 8\}$ the only known solution $816^2 = 665856$ is rather small. For base $B = 9$ there are 84 triples, where 20 triples are infeasible. The remaining 64 triples allow solutions. Moreover, for 8 triples we have found infinite patterns, see Appendix A for the details.

5 Suffixes and prefixes

For a given base B and n -*suffix* of an integer M consists of the last n digits of M in base B representation. Given a subset $D \subseteq \{0, 1, \dots, B - 1\}$ of the possible digits, we denote by $\omega_B^D(n)$ the number of positive integers x with at least n digits such that the last n digits of the corresponding square are contained in D . Let us have an example for $B = 10$ and $D = \{7, 8, 9\}$.

Since neither 7 nor 8 is a quadratic residue modulo 10, the last digit of the square has to be a 9, so that the last digit of the root is either a 3 or a 7, i.e., $\omega_{10}^{\{7,8,9\}}(1) = 2$. Using the notation and conditions from Lemma 1 we write

$$\left([a_{n-1}, \dots, a_0]_B\right)^2 = [c_{n-1}|b_{n-1}, \dots, b_0]_B$$

in order to indicate that the square M^2 of the integer $M = [a_{n-1}, \dots, a_0]_B$ ends with $[b_{n-1}, \dots, b_0]_B$ and has c_{n-1} as its next carryover. E.g. we have $[3]_{10}^2 = [0|9]_{10}$ and $[7]_{10}^2 = [4|9]_{10}$. Next we want to extend these 1-prefixes to 2-prefixes such that the last two digits of their corresponding squares are contained in $D = \{7, 8, 9\}$, i.e., we want to solve $[x, 3]_{10}^2 = [\star|y, 9]_{10}$ and $[x, 7]_{10}^2 = [\star|y, 9]_{10}$ for suitable $x \in \{0, \dots, 9\}$ and $y \in \{7, 8, 9\}$, where \star denotes an arbitrary (non-negative) integer. Using Lemma 1 we can rewrite the two equations to

$$2 \cdot 3 \cdot x + 0 = 6x + 0 \equiv y \in \{7, 8, 9\} \pmod{10} \quad \text{and} \quad 14x + 4 \equiv y \in \{7, 8, 9\} \pmod{10}.$$

Multiplying the equations with 7 and 3, respectively, and using the rem operator instead of \equiv , we can reformulate to

$$2x \text{ rem } 10 \in \{3, 6, 9\} \quad \text{and} \quad 2x + 2 \text{ rem } 10 \in \{1, 4, 7\} \Leftrightarrow 2x \text{ rem } 10 \in \{2, 5, 9\}.$$

Since 2 divides 10 we cannot further simplify these equations. Moreover, x is a solution iff $x + 10/2 = x + 5$ is a solution. In the first case only 6 is divisible by 2 and in the second case only 2 is divisible by 2, so that $x \in \{3, 8\}$ in the first case and $x \in \{1, 6\}$ in the second case. I.e., we have $[33]_{10}^2 = [1|89]_{10}$, $[83]_{10}^2 = [4|89]_{10}$, $[17]_{10}^2 = [1|89]_{10}$, $[67]_{10}^2 = [8|89]_{10}$, and $\omega_{10}^{\{7,8,9\}}(2) = 4$. Similar computations for the next digit gives

- $[x33]_{10}$: $6x + 10 \text{ rem } 10 \in \{7, 8, 9\} \Leftrightarrow 2x \text{ rem } 10 \in \{3, 6, 9\} \Rightarrow x \in \{3, 8\}$;
- $[x83]_{10}$: $6x + 68 \text{ rem } 10 \in \{7, 8, 9\} \Leftrightarrow 2x \text{ rem } 10 \in \{0, 3, 7\} \Rightarrow x \in \{0, 5\}$;
- $[x17]_{10}$: $14x + 2 \text{ rem } 10 \in \{7, 8, 9\} \Leftrightarrow 2x \text{ rem } 10 \in \{1, 5, 8\} \Rightarrow x \in \{4, 9\}$;
- $[x67]_{10}$: $14x + 44 \text{ rem } 10 \in \{7, 8, 9\} \Leftrightarrow 2x \text{ rem } 10 \in \{2, 5, 9\} \Rightarrow x \in \{1, 6\}$;

and $\omega_{10}^{\{7,8,9\}}(3) = 8$. Thus, we obtain $[333]_{10}^2 = [2|889]_{10}$, $[833]_{10}^2 = [5|889]_{10}$, $[083]_{10}^2 = [6|889]_{10}$, $[583]_{10}^2 = [9|889]_{10}$, $[417]_{10}^2 = [5|889]_{10}$, $[917]_{10}^2 = [12|889]_{10}$, $[167]_{10}^2 = [5|889]_{10}$, and $[667]_{10}^2 = [12|889]_{10}$. For general B , D and fixed last digit a_0 of the root the corresponding equations always have the form

$$(2a_0x + \gamma) \text{ rem } B \in D \tag{30}$$

for some suitable integer γ depending on the other data. If $2a_0$ is invertible in $\mathbb{Z}_B := \mathbb{Z}/B\mathbb{Z}$, then there are exactly $|D|$ solutions for x . In our situation a_0 cannot be invertible in \mathbb{Z}_{10} since

2 is zero divisor. However both choices $a_0 \in \{3, 7\}$ are invertible in \mathbb{Z}_{10} , so that the number of solutions is given by $2 \cdot |\{d \in D : d \equiv \gamma \pmod{2}\}|$, i.e., there are two solutions if γ is even and four solutions if γ is odd. So far only the first case occurred and the last digits of the square are uniquely determined. This changes when we extend the next digit and determine $\omega_{10}^{\{7,8,9\}}(4) = 24$. Computing the next values $\omega_{10}^{\{7,8,9\}}(n)$ with a computer program suggests:

Conjecture 2. For all $n \geq 3$ we have $\omega_{10}^{\{7,8,9\}}(n) = 8 \cdot 3^{n-3}$.

In Table 4 we list a few more such observations. Of course we may write for cases like $D = \{1, 3, 9\}$, where no 2-suffixes or no 3-suffixes exist at all, $\omega_{10}^D = 0 \cdot 3^{n-3}$ for $n \geq 3$. However, the existence of an integer k and a constant $c \in \mathbb{R}_{>0}$, depending on B and $D \subseteq \{0, 1, \dots, B-1\}$ with $|D| \geq 2$, such that $\omega_B^D(n) = c \cdot |D|^{n-k}$ for all $n \geq k$ seems to be wrong in general. For e.g. $B = 10$ and $D = \{0, 1, 6\}$ we have

$$\begin{aligned} (\omega_B^D)_{n=1, \dots, 20} &= 4, 12, 36, 112, 336, 1000, 3000, 8984, 26952, 80984, 243016, 728856, 2186568, \\ &6560856, 19682824, 59047960, 177146440, 531451096, 1594341000, 4783037336. \end{aligned}$$

Table 4: Conjectured formulas for $\omega_{10}^{\{d_1, d_2, d_3\}}(n)$

Proposition 3. If B is prime strictly larger than 2 and $D \subseteq \{0, 1, \dots, B-1\}$ with $|D| \geq 2$, then we have $\omega_B^D(n) = |D|^{n-1} \cdot \omega_B^D(1)$ for all $n \geq 1$.

Proof. Using Equation (30) it remains to observe that $2a_0$ is invertible in \mathbb{Z}_B since $a_0 \neq 0$ ($a_0 \neq 0 \pmod{B}$) and \mathbb{Z}_B is a (finite) field. ■

So, if $\omega_B^D(1) \neq 0$, which is just a question about the number of quadratic residues in D , then $\omega_B^D(n) = c \cdot |D|^n$ for some constant $c \in \mathbb{R}_{>0}$, i.e., asymptotically we have exponential behavior.

Conjecture 3. *If $B \in \mathbb{N}_{\geq 2}$ and $D \subseteq \{0, 1, \dots, B-1\}$ with $|D| \geq 2$, then there exists a constant $c \in \mathbb{R}_{>0}$ such that $\lim_{n \rightarrow \infty} \omega_B^D(n)/|D|^n = c$.*

In other words, for subsets D of cardinality 3 we conjecture that for each B and each D there exists a constant $c_{B,D} \in \mathbb{R}_{\geq 0}$ such that $\omega_B^D(n) \simeq c \cdot 3^n$. In Table 4 we can see that the value for c can differ significantly for different sets D, D' of allowed digits even if $\#D = \#D'$ and both sets allow n -suffixes for sufficiently large values of n .

Proposition 3 can be partially generalized. If x denotes the new digit, i.e., a_{2k} or a_{2k+1} in the following, then we have

$$B \cdot c_{2k} + b_{2k} = 2a_0x + 2 \sum_{i=1}^{k-1} a_i a_{2k-i} + a_k^2 + c_{2k-1} \quad (31)$$

$$B \cdot c_{2k+1} + b_{2k+1} = 2a_0x + 2 \sum_{i=1}^k a_i a_{2k+1-i} + c_{2k} \quad (32)$$

for $k \geq 1$. By $\widetilde{\omega}_B^D$ we denote the number of solutions counted by ω_B^D satisfying the additional condition that a_0 is invertible in $\mathbb{Z}/B\mathbb{Z}$.

Lemma 20. *Let $B \equiv 2 \pmod{4}$, $k \geq 1$, and $D \subseteq \{0, 1, \dots, B-1\}$.*

- (i) *The number of solutions with $x \equiv 0 \pmod{2}$ and a_0 odd equals the number of solutions with $x \equiv 1 \pmod{2}$ and a_0 odd.*
- (ii) *The number of solutions with $x \equiv 0 \pmod{2}$ and a_0 invertible in $\mathbb{Z}/B\mathbb{Z}$ equals the number of solutions with $x \equiv 1 \pmod{2}$ and a_0 invertible in $\mathbb{Z}/B\mathbb{Z}$.*
- (iii) *The number of solutions with $c_n \equiv 0 \pmod{2}$ and a_0 odd equals the number of solutions with $c_n \equiv 1 \pmod{2}$ and a_0 odd, where $n \in \{2k, 2k+1\} \setminus \{0\}$.*
- (iv) *The number of solutions with $c_n \equiv 0 \pmod{2}$ and a_0 invertible in $\mathbb{Z}/B\mathbb{Z}$ equals the number of solutions with $c_n \equiv 1 \pmod{2}$ and $\mathbb{Z}/B\mathbb{Z}$, where $n \in \{2k, 2k+1\} \setminus \{0\}$.*
- (v) *$\widetilde{\omega}_B^D(2k+2) = |D| \cdot \widetilde{\omega}_B^D(2k+1)$ for all $k \geq 1$.*
- (vi) *The number $\widetilde{\omega}_B^D(2k)$ splits equally into the four cases $(a_k \pmod{2}, c_{2k-1} \pmod{2}) \in \{0, 1\}^2$ for all $k \geq 2$.*
- (vii) *$\widetilde{\omega}_B^D(2k+1) = |D| \cdot \widetilde{\omega}_B^D(2k)$ for all $k \geq 2$.
If $\widetilde{\omega}_B^D(2k)$ splits evenly into $a_k + c_{2k-1} \equiv 0 \pmod{2}$ and $a_k + c_{2k-1} \equiv 1 \pmod{2}$, then $\widetilde{\omega}_B^D(2k+1) = |D| \cdot \widetilde{\omega}_B^D(2k)$.*

Proof. If a_0 is invertible in $\mathbb{Z}/B\mathbb{Z}$, then $B \equiv 0 \pmod{2}$ implies that a_0 is odd. So, if x is a solution, so is $x + B/2$. This already gives (i), (ii), (iii), and (iv) since $B/2 \equiv 1 \pmod{2}$ and

$2a_0 \cdot B/2 \equiv B \pmod{2B}$ using that a_0 is odd. For (v) note that $\omega_B^D(2k+1)$ splits evenly into $c_{2k} \equiv 0 \pmod{2}$ and $c_{2k} \equiv 1 \pmod{2}$ if $k > 0$. Since a_0 is invertible in $\mathbb{Z}/B\mathbb{Z}$, for each $b_{2k+1} \in D$ we have $2 \cdot \widetilde{\omega}_B^D(2k+1)/2$ solutions. For (vi) we consider the situation when the digit a_k is determined by a solution x . From (ii) we conclude that those cases split equally onto $a_k \pmod{2} \in \{0, 1\}$. Now we further have to extend those k -digit numbers to $2k$ -digit numbers. During this process the digit a_k does not change any more, while the parities of the subsequent carryovers split half-half due to (iv). Applied iteratively, we end up with statement (vi). For (vii) we observe that (vi) implies that $\widetilde{\omega}_B^D(2k)$ splits evenly into $a_k + c_{2k-1} \equiv 0 \pmod{2}$ and $a_k + c_{2k-1} \equiv 1 \pmod{2}$, so that we can proceed as for (v). ■

Observe that $[3]_{10}^2 = [0|9]_{10}$ and $[7]_{10}^2 = [4|9]_{10}$, i.e., for $c_1 \equiv 0 \pmod{2}$ there are two and for $c_1 \equiv 1 \pmod{2}$ there is none possibility. Additionally a_1 is odd in both cases and $\omega_{10}^{\{7,8,9\}}(3) = 2 \cdot \omega_{10}^{\{7,8,9\}}(2)$. So, statements (i), (ii), (iii), and (iv) are valid for $n \geq 1$ only. Also the condition that a_0 is odd is crucial. For $D = \{0, 4, 8\}$ consider e.g. the ‘‘pair’’ of solutions 002 and 502 with 3 digits. We have $[002]_{10}^2 = [0|004]_{10}$ and $[502]_{10}^2 = [2|004]_{10}$, i.e., both carryovers are even. And indeed, those two solutions with 3 digits generate 12 solutions with 4 digits and not $2 \cdot 3 = 6$ as the argument in the proof of (v) would suggest. Indeed $\omega_{10}^{\{0,4,8\}}(4) = 144 \neq 3 \cdot 36 = 3 \cdot \omega_{10}^{\{0,4,8\}}(3)$.

Corollary 2. *Let $B \equiv 2 \pmod{4}$, $k \geq 1$, and $D \subseteq \{0, 1, \dots, B-1\}$. Then, for each $n \geq 3$ we have $\widetilde{\omega}_B^D(n) = |D|^{n-3} \cdot \widetilde{\omega}_B^D(3)$.*

Let us denote the number of solutions $x \in \{1, \dots, B-1\}$ with $x^2 \equiv a \pmod{B}$ by $s_B(a)$.⁸ Clearly we have

$$\omega_B^D(1) = \sum_{d \in D} s_B(d), \quad (33)$$

where $s_B(0) = 0$ for all $B \geq 2$. Note that we have $\widetilde{\omega}_B^D(n) = \omega_B^D(n)$ for all $n \geq 1$ iff $\widetilde{\omega}_B^D(1) = \omega_B^D(1)$. Let us have a closer look at the special case $B = 10$. Here the non-zero quadratic residues are given by $\{1, 4, 5, 6, 9\}$. So, if e.g. $D \cap \{1, 4, 5, 6, 9\} = \emptyset$, then $\omega_{10}^D(n) = 0$ for all $n \geq 1$. Corollary 2 implies:

Proposition 4. *If $B = 10$ and $D \subseteq \{0, 1, \dots, B-1\}$ with $D \cap \{4, 5, 6\} = \emptyset$, then we have $\widetilde{\omega}_B^D(n) = \omega_B^D(n)$ for all $n \geq 1$ and $\omega_B^D(n) = |D|^{n-3} \cdot \omega_B^D(3)$ for all $n \geq 3$.*

So, especially Conjecture 2 and several other cases of Table 4 are true. Lemma 16 indicates that $\omega_{10}^{\{0,1,2\}}(n)$ is closely related with $\omega_{10}^{\{0,4,8\}}(n)$ while the number of digits can change when going from N to $2N$.

Our next aim is to define a counting function $\alpha_B^D(n)$ for n -prefixes similar to ω_B^D for n -suffixes. Before we give a definition of an n -prefix, we study a few examples. Suppose we

⁸Using the Chinese remainder theorem we can reduce the problem to prime powers and then to primes B . For odd primes the Legendre-symbol and the quadratic reciprocity law comes into play.

want the 2-prefix to be 41. If only 4-digit squares are allowed, then

$$\sqrt{4100} = 64.03124237 \quad \text{and} \quad \sqrt{4199} = 64.79969136$$

shows that there is no such integer. However, if we allow 5-digit squares, then

$$\sqrt{041000} = 202.4845673 \quad \text{and} \quad \sqrt{041999} = 204.9365756$$

shows that we have the following two solutions

$$203^2 = 41209 \quad \text{and} \quad 204^2 = 41616$$

both having [4, 1] as their leading two digits.

Lets us have another example and search for a number whose square starts with 569569. From

$$\sqrt{569569000000} = 754697.9528 \quad \text{and} \quad \sqrt{569569999999} = 754698.6153$$

we conclude that 754698 is a solution, i.e., $754698^2 = 569569071204$ starts with 569569. Similarly,

$$\sqrt{05695690000000} = 2386564.476 \quad \text{and} \quad \sqrt{05695699999999} = 2386566.571$$

gives us the solutions

$$2386565^2 = 5695692499225 \quad \text{and} \quad 2386566^2 = 5695697272356.$$

In order to try to explain a few things we observe that

$$\sqrt{x \cdot C + (C - 1)} - \sqrt{x \cdot C} \tag{34}$$

is monotonically decreasing in x for each $C > 0$. We will choose $C = B^k$, where B is the basis, and will assume suitable bounds for x . Next we observe

$$\sqrt{s+t} - \sqrt{s} = \frac{t}{\sqrt{s+t} + \sqrt{s}} \tag{35}$$

for all $s, t > 0$. Note that the denominator of the right hand side is bounded between $\max\{2\sqrt{t}, \sqrt{s}\}$ and $2\sqrt{s+t}$.

For our first cases, i.e. squares without a ‘‘leading zero’’ we have to choose $C = B^k$ for some positive integer k and $B^{k-1} \leq x \leq B^k - 1$. With this we obtain

$$\frac{1}{2} \leq \sqrt{x \cdot C + (C - 1)} - \sqrt{x \cdot C} < \sqrt{B}, \tag{36}$$

i.e., we cannot guarantee a solution but there may be several solutions. For the second case we have to choose $C = B^{k+1}$ for some positive integer k and $B^{k-1} \leq x \leq B^k - 1$. With this we obtain

$$\frac{\sqrt{B}}{2} \leq \sqrt{x \cdot C + (C - 1)} - \sqrt{x \cdot C} < B, \quad (37)$$

i.e. for $B \geq 5$ we can always guarantee a solution, while the total number of solutions is upper bounded by B . Note that these estimations are valid for every sequence of leading digits, i.e., no special properties are used. So, if $0 \notin D$, then there are exactly $|D|^n$ squares and if $0 \in D$ there are exactly $(|D| - 1) \cdot |D|^{n-1}$ squares with the leading digits in D (including the possibility of a leading 0), provided that B is sufficiently large.

Definition 2. By α_B^D we denote the number of integers $B^{n-\frac{1}{2}} \leq x < B^{n+\frac{1}{2}}$ such that the first n digits in base B of x^2 are contained in D .

From the above we conclude

$$\left\lfloor \frac{\sqrt{B}}{2} \right\rfloor \cdot |D|^n \leq \alpha_B^D(n) \leq \left(\left\lfloor \frac{\sqrt{B}}{2} \right\rfloor + B \right) \cdot |D|^n. \quad (38)$$

Conjecture 4. If $B \in \mathbb{N}_{\geq 2}$ and $D \subseteq \{0, 1, \dots, B-1\}$ with $|D| \geq 2$, then there exists a constant $c \in \mathbb{R}_{>0}$ such that $\lim_{n \rightarrow \infty} \alpha_B^D(n)/|D|^n = c$.

6 Search algorithms

Suppose that $P_{B,D}(n)$ is a list of all numbers $x < B^n$ such that the last n digits of x^2 in base B are contained in D . We can easily compute $P_{B,D}(n+1)$ from $P_{B,D}(n)$ by prepending another suitable digit. As shown in Section 5 the possibilities for the new digit do not need to be tried but can be computed. If we utilize the recursion from Lemma 1 and also store the carryovers, then $P_{B,D}(n)$ can be computed in $\#P_{B,D}(n) \cdot O(n)$ operations, which equals $O(n \cdot |D|^n)$ operations if Conjecture 3 is true. If we use depth-first search than the space requirement is just $O(n)$. We may also compute all n -digit number in base B such that their squares consist of digits in D only. To this end we have just compute the leading n digits for all elements of $P_{B,D}(n)$ using the recursion from Lemma 1. Since the number of candidates while decrease asymptotically, the algorithm will still need $\#P_{B,D}(n) \cdot O(n)$ operations only.

For exhaustive lists of n -prefixes we just have to loop over all $|D|^n$ choices for the leading n digits of the square and compute bounds for the square roots. From Inequality (4) we conclude that $n \cdot |D|^n$ operations are needed. Again, if we use depth-first search than the space requirement is just $O(n)$.

Since the conjectures order of magnitude of $\omega_B^D(n)$ as well as $\alpha_B^D(n)$ is $O(|D|^n)$, computing the first s digits using prefixes and the last $n-s$ digits using suffixes, we end up with $O(n \cdot |D|^n)$ operations, i.e., $O(n \cdot 3^n)$ operations in our situation where $\#D = 3$. Slightly more sophisticated,

we can compute lists of p -digit prefixes and s -digit suffixes, so that they overlap in q digits, see e.g. <http://djm.cc/rpa-output/arithmatic/digits/squares/three.digits.s>. Sticking to $\#D = 3$ and assuming the truth of Conjecture 3, the computation of the two lists need $O(n \cdot 3^p)$ and $O(n \cdot 3^s)$ operations, respectively. If we assume that the overlaps scatter almost evenly over the 10^q possible buckets for $B = 10$, then combining all possibilities needs $O(n \cdot 3^{p+s}/10^q)$ operations. Choosing $p = s = \ln 10 / (2 \ln 10 - \ln 3) \cdot n$ and $q = \ln(3) / \ln(10) \cdot n$ yields a search algorithm that needs roughly $O(n \cdot 3^{0.657n})$ operations. The big drawback is that the space requirements are of the same order of magnitude. However, if we compute lists of k -suffixes, k -prefixes, loop over all $O(3^{2k})$ combinations, and apply the just described algorithm for the central n digits, then we end up with a search algorithm using $O((n+k) \cdot 3^{2k+0.657n})$ operations and $O(n \cdot 3^{0.657n})$ space for checking all numbers with at most $n + 2k$ digits.

Let us consider the following heuristic argument. For a given base $B \geq 2$ and a subset $D \subseteq \{0, 1, \dots, B-1\}$ of allowed digits we assume that there exist constants $c_1, c_2 \in \mathbb{R}_{\geq 0}$ such that the number of k -suffixes is roughly $c_1 \cdot |D|^k$ and the number of m -prefixes is roughly $c_2 \cdot |D|^m$. Combining an m -prefix with a k -suffix gives an n -digit root r , where $n = m + k$. By construction the last k digits of r^2 are contained in D . If the carryovers don't interfere, then also the first m digits of r^2 are contained in D . Noting that r^2 contains either $2n - 1$ or $2n$ digits, the $n - 1$ or n digits in the center have to be checked. For each digit we assume an independent probability of $|D|/B$. Under this assumptions the expectation for an n -digit root r with $\omega_B(r^2) = D$ is given by

$$c_1 c_2 |D|^n \cdot \left(\frac{|D|}{B}\right)^{n-s} = c_1 c_2 \cdot \frac{|D|^{2n-s}}{B^{n-s}}, \quad (39)$$

where $s \in \{0, 1\}$. For simplicity we assume $s = 0$, so that the expectation is roughly $c_1 c_2 \left(\frac{|D|^2}{B}\right)^n$. By summing we conclude that the expected number of root solutions with at least n digits is given by

$$c_1 c_2 \left(\frac{|D|^2}{B}\right)^n \cdot \frac{B}{B - |D|}. \quad (40)$$

For $B = 10$ and $|D| = 3$ this expectation tends to zero for increasing n , so that the existence of infinite patterns shows that our independence assumption is wrong in general. Nevertheless the corresponding estimations are not too bad in many cases as shown exemplarily in Table 5. Here we have chosen the values for c_1 and c_2 according to the number of 10-suffixes and 10-prefixes. We give counts for the number of sporadic root solutions of length 25 or length between 10 and 25. Estimations are stated for the cases of 20-, > 25, and 10 – 25 digits. Removing the solutions from infinite patterns certainly has an effect, so that we mark the triples D of allowed digits that permit infinite patterns in bold face. Triples D where $c_1 c_2$ is relatively large allow infinite patterns in many cases. A notably exception is $D = \{1, 4, 6\}$, which seems to allow no infinite pattern but many sporadic solutions. Here we have $c_1 c_2 =$

D	c_1	c_2	# 25-digit	est. 20-digit	est. > 25-digit	est. 10 – 25-digit	# 10 – 25-digit

Table 5: Estimations for the number of sporadic solutions.

7.82, the estimated number of solutions with 10 – 25 digits is 22.22 and there are indeed 21 of them. The estimation for the number of solutions with more than 25 digits is even as large as 5.05, so that searching more extensively seems to make sense.

Appendix

A Results for base $B = 9$

In Table 6 we list a few infinite patterns in base $B = 9$. Since $B = 3^2$ we have $\varphi_9((3N)^2) = \varphi_9(N^2) \cup \{0\}$. So, for the cases $0 \in D$ of allowed digits we assume that 3 does not divide N . A corresponding “dual pattern” always exists and can be constructed easily. For applications of Theorem 1 with $u = 1$ we only give three examples. Due to the relation between examples with decimal digits in $\{0, 1, 2\}$ and those with decimal digits in $\{0, 4, 8\}$, see Lemma 16, we have dropped the patterns for the latter. Patterns constructed by Lemma 12 come in pairs if $r \neq s$ and we only state the examples with $r \leq s$ or $r > s$ if s would be divisible by 3 otherwise.

Lemma 21. For $B = 9$ let

$$N_1 = \left[\underbrace{1, 0, \dots, 0}_{k \text{ times}}, \underbrace{2, 0, \dots, 0}_{n \text{ times}}, \underbrace{2, 0, \dots, 0, 1}_{k \text{ times}} \right]_B = 1 + 2 \cdot B^{k+1} + 2 \cdot B^{n+k+2} + 1 \cdot B^{n+2k+3}$$

and

$$N_2 = \left[\underbrace{2, 0, \dots, 0}_{k \text{ times}}, \underbrace{1, 0, \dots, 0}_{n \text{ times}}, \underbrace{1, 0, \dots, 0, 2}_{k \text{ times}} \right]_B = 2 + 1 \cdot B^{k+1} + 1 \cdot B^{n+k+2} + 2 \cdot B^{n+2k+3}.$$

Then, N_1^2 and N_2^2 have digits in $\{0, 1, 4\}$ in base B if

$$k + n + 2, 2k + 2, 2k + n + 3, 2k + n + 4, 2k + 2n + 4, \text{ and } 3k + n + 4$$

Table 6: Explanations for some infinite patterns in base $B = 9$.

are pairwise different. The conditions are e.g. satisfied if $k > n$.

Proof. We have

$$N_1^2 = 1 + 4 \cdot B^{k+1} + 4 \cdot B^{k+n+2} + 4 \cdot B^{2k+2} + 10 \cdot B^{2k+n+3} + 4 \cdot B^{2k+2n+4} + 4 \cdot B^{3k+n+4} + 4 \cdot B^{3k+2n+5} + 1 \cdot B^{4k+2n+6}$$

and

$$N_2^2 = 4 + 4 \cdot B^{k+1} + 4 \cdot B^{k+n+2} + 1 \cdot B^{2k+2} + 10 \cdot B^{2k+n+3} + 1 \cdot B^{2k+2n+4} + 4 \cdot B^{3k+n+4} + 4 \cdot B^{3k+2n+5} + 4 \cdot B^{4k+2n+6}.$$

In base $B = 9$ we can replace the terms $10 \cdot B^{2k+n+3}$ by $1 \cdot B^{2k+n+3} + 1 \cdot B^{2k+n+4}$. Note that the pairs of exponents that are not mentioned in the statement cannot coincide. ■

Lemma 22. For each $n \geq 2$ and $B = 9$ the integer

$$N = 1 + 1 \cdot B^n + 4 \cdot B^{2n} + 1 \cdot B^{3n} + 1 \cdot B^{4n} \quad (41)$$

satisfies $D_B(N^2) = \{0, 1, 2\}$.

Proof. We compute

$$N^2 = 1 + 2 \cdot B^n + 9 \cdot B^{2n} + 10 \cdot B^{3n} + 20 \cdot B^{4n} + 10 \cdot B^{5n} + 9 \cdot B^{6n} + 2 \cdot B^{7n} + B^{8n},$$

so that $9 = 1 \cdot 9 + 0$, $10 = 1 \cdot 9 + 1$, and $20 = 2 \cdot 9 + 2$ imply the stated result. ■

Lemma 23. For $B = 9$ let

$$N = 1 + 5 \cdot B^k + (B^{k-1} - 1) \cdot B^{k+1}. \quad (42)$$

If $k \geq 2$, then $\varphi_9(N^2) = \{0, 1, B - 1\} = \{0, 1, 8\}$.

Proof. We compute

$$\begin{aligned} N^2 &= 1 + 10 \cdot B^k - 2 \cdot B^{k+1} + 27 \cdot B^{2k} - 10 \cdot B^{2k+1} + B^{2k+2} + 10 \cdot B^{3k} - 2 \cdot B^{3k+1} + B^{4k} \\ &\stackrel{B=9}{=} 1 + 1 \cdot B^k - 1 \cdot B^{k+1} + 2 \cdot B^{2k+1} + 1 \cdot B^{3k} - 1 \cdot B^{3k+1} + B^{4k} \\ &= 1 + 1 \cdot B^k + B^{k+1} \cdot (B^k - 1) + 1 \cdot B^{2k+1} + 1 \cdot B^{3k} + B^{3k+1} \cdot (B^{k-1} - 1). \end{aligned}$$

The sequences $B^x \cdot (B^y - 1)$ correspond to a sequence of y times digit $B - 1 = 8$. Note that for $k \geq 2$ the indicated digits 1 and 8 do not interfere. ■

Lemma 24. For $B = 9$ let

$$N = 1 + 5 \cdot B^k + (B^{k-1} - 1) \cdot B^{k+1} + B^m. \quad (43)$$

If $k \geq 2$ and $3k + 1 \leq m < 4k$, then $\varphi_9(N^2) = \{0, 1, B - 1\} = \{0, 1, 8\}$.

Proof. We compute

$$\begin{aligned}
N^2 &= 1 + 10 \cdot B^k - 2 \cdot B^{k+1} + 27 \cdot B^{2k} - 10 \cdot B^{2k+1} + B^{2k+2} + 10 \cdot B^{3k} - 2 \cdot B^{3k+1} + 2 \cdot B^m + B^{4k} \\
&\quad + 10 \cdot B^{m+k} - 2 \cdot B^{m+k+1} + 2 \cdot B^{m+2k} + B^{2m} \\
&\stackrel{B \equiv 9}{=} 1 + 1 \cdot B^k - 1 \cdot B^{k+1} + 2 \cdot B^{2k+1} + 1 \cdot B^{3k} - 1 \cdot B^{3k+1} + 2 \cdot B^m + B^{4k} \\
&\quad + 1 \cdot B^{m+k} - 1 \cdot B^{m+k+1} + 2 \cdot B^{m+2k} + B^{2m} \\
&= 1 + 1 \cdot B^k + B^{k+1} \cdot (B^k - 1) + 1 \cdot B^{2k+1} + 1 \cdot B^{3k} + B^{3k+1} \cdot (B^{m-3k-1} - 1) + 1 \cdot B^m + 1 \cdot B^{4k} \\
&\quad + 1 \cdot B^{m+k} + B^{m+k+1} \cdot (B^{k-1} - 1) + 1 \cdot B^{m+2k} + 1 \cdot B^{2m}.
\end{aligned}$$

The sequences $B^x \cdot (B^y - 1)$ correspond to a sequence of y times digit $B - 1 = 8$. Note that $k - 1, m - 3k - 1 \geq 0$ and $m < 4k < m + k$, so that the indicated digits 1 and 8 do not interfere. ■

B Squares with just two digits in base $B = 10$

In this section we want to briefly summarize the known results on positive integers N such are not divisible by 10 but satisfy $|\omega_{10}(N^2)| = 2$. The only known examples are given by

$$4, 5, 6, 7, 8, 9, 11, 12, 15, 21, 22, 26, 38, 88, 109, 173, 212, 235, 264, 3114, 81619,$$

see e.g. <https://oeis.org/A016070> and [2, Entry 109]. The corresponding squares are given by

$$16, 25, 36, 49, 64, 81, 121, 144, 225, 441, 484, 676, 1444, 7744, 11881, 29929, 44944, 55225, 69696, 969696, 6661661161.$$

Below 10^{41} every other square either ends with zero or contains at least three different digits. Given the heuristic argument in Section 6, it is very unlikely that further examples exist.

There are exactly 22 possibilities for the last two decimal digits:

$$01, 04, 09, 12, 14, 16, 18, 24, 25, 29, 34, 36, 33, 45, 46, 47, 48, 49, 56, 67, 69, 89,$$

i.e., the last two digits already determine $\varphi_{10}(N^2)$ except when the square ends with 44. For some construction principles for infinite patterns, as described in Section 3, it can be easily shown that no such example exists for just two different decimal digits. With respect to Lemma 12 we remark that the parameters r and s itself have to satisfy $|\varphi_{10}(r^2) \setminus \{0\}| = |\varphi_{10}(s^2) \setminus \{0\}| = 1$, which just leaves the cases $r, s \in \{1, 2, 3\}$.
